Note au lecteur

Ce rapport a été préparé et les travaux mentionnés dans ce rapport ont été entrepris par AtkinsRéalis Canada inc. (AtkinsRéalis), pour l'usage exclusif de Ressources PMET Inc. (PMET), qui a été partie à l'élaboration de l'étendue des travaux et en comprend les limites. La méthodologie, les constatations, les conclusions et les recommandations de ce rapport sont basées uniquement sur la portée des travaux et sont soumises aux considérations de temps et de budget décrites dans la proposition et/ou le contrat en vertu duquel ce rapport a été publié. L'utilisation du présent rapport par un tiers, la confiance qu'il accorde à celui-ci ou la décision qu'il prend en se fondant sur celui-ci sont la responsabilité exclusive de ce tiers. AtkinsRéalis n'assume aucune responsabilité à l'égard des dommages qui pourraient être subis ou engagés par un tiers en raison de l'utilisation de ce rapport, de la confiance accordée à celui-ci ou de toute décision prise en fonction de celui-ci.

Les constatations, conclusions et recommandations contenues dans ce rapport (i) ont été élaborées d'une manière conforme au niveau de compétence normalement exercé par les professionnels exerçant actuellement dans des conditions similaires dans la région, et (ii) reflètent le meilleur jugement de AtkinsRéalis basé sur les informations disponibles au moment de la préparation de ce rapport. Aucune autre garantie, expresse ou implicite, n'est donnée à l'égard des services professionnels fournis à PMET ou des constatations, conclusions et recommandations contenues dans le présent rapport. Les constatations et les conclusions contenues dans le présent rapport ne sont valables qu'à la date du présent rapport et peuvent être fondées, en partie, sur des renseignements fournis par d'autres personnes. Si l'une ou l'autre des informations est inexacte, de nouvelles informations sont découvertes ou les paramètres du projet changent, des modifications au présent rapport pourraient être nécessaires.

Ce rapport doit être lu dans son ensemble, car des sections prises hors contexte peuvent être trompeuses. Si des divergences surviennent entre la version préliminaire (ébauche) et la version finale de ce rapport, c'est la version finale qui prime. Rien dans le présent rapport ne vise à constituer ou à fournir une opinion juridique.

Le contenu de ce rapport est confidentiel et exclusif. Sauf par PMET, il n'est pas permis de reproduire ou de distribuer le présent rapport ou d'utiliser l'information contenue dans les présentes, en totalité ou en partie, ou de s'y fier, sans la permission expresse écrite de PMET et de AtkinsRéalis.

Annexe A. Résultats des essais cinétiques

1. Introduction

AtkinsRéalis a été mandatée par Innova, une filiale québécoise entièrement détenue par Ressources PMET inc., pour réaliser une étude de faisabilité optimisée pour la gestion des résidus miniers et de l'eau pour le projet minier Shaakichiuwaanaan. Le site est situé dans la région d'Eeyou Istchee Baie-James, dans la province de Québec. Il se trouve à environ 220 km à l'est de Radisson et à environ 240 km au nord-nord-est de Nemaska. Le projet permettra d'extraire du spodumène d'un gisement de pegmatite à l'aide d'une méthode hybride combinant l'exploitation à ciel ouvert et l'exploitation souterraine. La durée d'exploitation du projet est actuellement estimée à 23 ans.

1.1 Contexte

La caractérisation des propriétés géochimiques des matériaux miniers qui seront produits lors de l'exploitation du gisement a été entreprise depuis 2023. La plupart des analyses réalisées jusqu'à présent sur les lithologies stériles, le minerai et les résidus miniers de procédé ont été présentées dans le rapport de Vision Geochemistry (2025). Toutefois, la classification des différents lithologies et matériaux miniers selon les critères du Guide de caractérisation des résidus miniers et du minerai (MELCC, 2020), ci-après GCRMM, n'a pas été complétée. De plus, des informations requises, telles que la composition minéralogique des matériaux miniers et les résultats des essais de lixiviation en colonne sur les stériles n'étaient également pas inclus dans le document.

La présente étude vise à valider les hypothèses émises dans le rapport de Vision Geochemistry (2025), à compléter les résultats de caractérisation géochimique des matériaux miniers du projet et, par conséquent, à mettre à jour leur classification selon les critères du GCRMM sur la base de l'information disponible en date de ce rapport.

1.2 Objectif de l'étude

L'objectif de la présente note technique est de valider et mettre à jour l'interprétation des données de caractérisation géochimique de matériaux miniers du projet Shaakichiuwaanaan selon la méthodologie du GCRMM. Les matériaux pourront être ainsi classifiés selon les différentes catégories décrites dans le guide (acidogènes, lixiviables, etc.), permettant ainsi d'évaluer l'impact potentiel sur l'environnement lors de leur entreposage en surface.

Cette note comprend également des résultats d'analyse qui n'avaient pas été présentés antérieurement. Il s'agit de la composition minéralogique des matériaux ainsi que des résultats d'essais de lixiviation en colonne réalisés dans le cadre d'un doctorat de l'Université du Québec en Abitibi-Témiscamingue (UQAT).

2. Programme de caractérisation

2.1 Échantillonnage

Au total, 350 échantillons ont été sélectionnés sur des carottes de forage d'exploration et analysés au laboratoire. Le détail de la sélection des échantillons est présenté dans Vision (2025). La stratégie d'échantillonnage visait à capturer la variabilité spatiale et compositionnelle des matériaux miniers. Parmi ces échantillons, 316 étaient des échantillons de stériles appartenant à quatre types lithologiques : amphibolite, métasédiments, pegmatite stérile et roches ultramafiques. À ceux-ci s'ajoutent des échantillons de minerai de pegmatite à spodumène (25) et de résidus miniers (9). Tous ces matériaux miniers ont été soumis à des tests statiques et cinétiques afin de déterminer leur capacité à générer de l'acidité et à lixivier des métaux (Vision Geochemistry, 2025).

2.2 Programme analytique

L'ensemble de ces matériaux a été soumis à divers volets d'analyses, incluant des essais de détermination du potentiel de génération d'acide, des essais de lixiviation, des essais cinétiques et des caractérisations minéralogiques. Le **Tableau 2-1** présente la répartition détaillée du nombre d'échantillons analysés pour chaque type de test selon la lithologie. Une partie de ces analyses a été détaillée dans l'étude de Vision Geochemistry (2025), c'est notamment le cas des essais statiques, et d'une partie des essais en colonne. À cela s'ajoutent les essais en colonne effectués par l'UQAT sur l'ensemble des lithologies du projet, ainsi que les résultats sur la minéralogie de la majorité de ces dernières.

Tableau 2-1 Programme analytique des lithologies du projet

Lithologie	PGA (1)	Métaux extractibles (2)	Essais de lixiviation				Minéralogie	
			SPLP et CTEU-9 (3)	TCLP (3)	Cellules humides	Colonnes	DRX	TIMA
Amphibolite	128	128	128	41	5+1dup	3	7	2
Métasédiments	101	101	101	50	3	2	1	1
Ultramafique	54	54	54	8	3	2	2	3
Pegmatite	33	33	33	13	2	1	90	-

Résidus miniers	9	9	9	9	-	5+1dup.	-	-

Notes :

1. *Potentiel de génération d'acide – Sobek modifié ;*
2. *La méthode CEAEQ MA 200 Mét. 1.2 (digestion partielle) permet d'analyser la teneur en métaux extractibles dans les échantillons ;*
3. *Méthode MA100 Lix.com : SPLP : essai de lixiviation simulant les pluies acides, CTEU-9 : essai à l'eau déionisée, TCLP : essai de lixiviation à l'acide acétique.*

Les essais cinétiques réalisés sur les matériaux produits par le projet minier sont décrits dans les sections suivantes.

2.2.1 Essais en cellules humides (Vision Geochemistry, 2025)

La configuration de ces essais est décrite dans le rapport de Vision, et est également normée par l'ASTM (ASTM D5744). Il est donc possible de se référer à ces documents pour plus d'information. En tout, 15 essais en cellules humides ont été réalisés. La sélection des échantillons a été réalisée afin de couvrir les intervalles de teneurs en soufre et en arsenic observés dans les différentes lithologies ainsi que divers potentiels de génération d'acide tels que déterminés de façon préliminaire lors des essais statiques. Ces essais se sont déroulés sur une période de 100 semaines. Le **Tableau 2-2** présente la liste des essais réalisés ainsi que les paramètres qui ont guidé la sélection des échantillons.

Tableau 2-2 Liste des échantillons soumis aux essais en cellules humides

Nom de l'échantillon	Lithologie	Paramètres de sélection des échantillons		
		% $S_{sulfure}$	Potentiel de génération d'acide selon les essais statiques	Teneur en arsenic (ppm)
CV5-WR-HCT-2	Amphibolite	1,12	PGA	33
CV5-WR-HCT-5	Amphibolite	0,62	PGA	150
CV5-WR-HCT-14	Amphibolite	0,08	NPGA	11
CV5-WR-HCT-22	Amphibolite	0,04	NPGA	46
CV5-WR-HCT-33	Amphibolite	0,05	NPGA	5,9
CV5-WR-HCT-36	Ultramafique	0,12	NPGA	440
CV5-WR-HCT-39	Métasédiments	0,90	PGA	42
CV5-WR-HCT-50	Métasédiments	0,21	NPGA	100
CV5-WR-HCT-56	Métasédiments	0,58	PGA	13
CV5-WR-HCT-59	Ultramafique	0,04	NPGA	92
CV5-WR-HCT-62	Ultramafique	0,04	NPGA	880
CV5-WR-HCT-64	Pegmatite	0,04	NPGA	14
CV5-WR-HCT-69	Pegmatite	0,04	NPGA	7,2
CV5-WR-HCT-74	Pegmatite à spodumène	0,27	NPGA	17
CV5-WR-HCT-76	Pegmatite à spodumène	0,15	NPGA	3,8

Note : PGA : Potentiellement générateur d'acidité ; NPGA : Potentiellement non générateur d'acidité

2.2.2 Essais en colonnes sur les résidus miniers de procédé (Vision Geochemistry, 2025)

Des essais de lixiviation en colonne ont été réalisés sur des échantillons de résidus miniers issus de différentes étapes du procédé ainsi qu'un composite de l'ensemble de ces échantillons. Les résultats sont disponibles pour vingt semaines d'essai pour cinq échantillons de résidus miniers (Vision Geochemistry, 2025).

- CV5-CL-1 : résidus du procédé de flottation ;
- CV5-CL-2 : composé intermédiaire du procédé ("middlings") ;
- CV5-CL-3 : résidus issus de la séparation magnétique ;
- CV5-CL-4 : résidus du "bypass" ;
- CV5-CL-5 : composite représentatif des futurs résidus de procédés qui seront entreposés sur le site. Un duplicata de cet échantillon a été testé, dans le but de contrôler la validité des résultats.

Des échantillons de 30 cm de hauteur ont été testés dans des colonnes de 15 cm de diamètre (environ 8,5 kg de matériel par colonne). Elles ont été réalisées en conditions drainées. Les rinçages ont été réalisés avec 2 litres d'eau déionisée tous les 15 jours. Le détail de ces essais est disponible dans le rapport de Vision Geochemistry (2025).

2.2.3 Essais en colonnes sur les stériles (UQAT)

Ces essais en colonne ont été réalisés sur les différentes lithologies stériles du gisement. Ils ont été réalisés dans le cadre du projet doctoral de madame Neila Seray sous la direction du professeur Benoît Plante de l'Université du Québec en Abitibi-Témiscamingue (UQAT) en collaboration avec PMET. Les échantillons ont été mis à l'essai soit en conditions drainées, soit en conditions submergées, afin de simuler différents scénarios d'entreposage potentiels. Chaque colonne contient un échantillon unique ou un mélange de lithologies, avec des masses variant d'environ 16 à 20 kg selon les matériaux. Elles sont de forme cylindrique, d'un mètre de longueur et de 14 cm de diamètre. Un géotextile est placé à leur base afin d'éviter la perte de matériaux fins. La configuration de chaque colonne est décrite dans le **Tableau 2-3**. Les échantillons sont principalement des composites des échantillons de carottes de forage qui ont été utilisés pour les essais en cellules humides décrites dans la **Section 2.2.1**. Les quantités de matériel ayant été insuffisantes pour obtenir le poids visé pour chaque colonne, celles-ci ont été complétées par des masses de 1,9 à 9,8 kg de rejets de forage.

Tableau 2-3 Description des essais cinétiques en colonnes pour les stériles (UQAT)

Colonne	Lithologie − Échantillons HCT	Condition	Masse finale dans la colonne
C1	Amphibolite PAG − HCT-5	drainée	≈ 17 kg
C2	Amphibolite NPAG − HCT-22	drainée	≈ 16 kg
C3	Ultramafique − HCT-36 / 59 / 62	drainée	≈ 20 kg
C4	Métasédiments − HCT-39 / 50	drainée	≈ 18 kg
C5	Pegmatite stérile − HCT-64 / 69	drainée	≈ 20 kg
C6	Mélange amphibolite − HCT-5 / 22	drainée	≈ 20 kg
C7	Métasédiments − HCT-39 / 50	submergée	≈ 18 kg
C8	Ultramafique − HCT-36 / 59 / 62	submergée	≈ 20 kg
C9	Mélange de toutes les lithologies stériles en proportions représentatives des matériaux extraits par le projet	drainée	≈ 20 kg

Le rinçage des colonnes a été réalisé tous les 15 jours, sur une période d'un an, excepté pour les colonnes C1 (amphibolite PAG) et C2 (amphibolite NPAG) dont les rinçages ont été réalisés sur une période de 6 mois. Par la suite, les deux échantillons ont été mélangés dans les proportions représentatives des matériaux extraits pour le projet et l'essai en colonne s'est poursuivi pendant 6 mois supplémentaires (colonne C6). La majorité des rinçages a été effectuée avec 1,8 L d'eau déionisée, à deux exceptions près : un volume réduit de 50 % aux rinçages 10 et 11 et un volume augmenté de 200 % aux rinçages 15 et 16. Enfin, les colonnes ont été placées à basse température (4 °C) pour les rinçages 22 et 24.

3. Critères comparatifs

Le Guide de caractérisation des résidus miniers et du minerai (ci-après, GCRMM), publié par le MELCC en juin 2020 et la Directive 019 (MELCCFP, 2025) considèrent que, à l'exception de l'effluent final, les substances liquides ou solides générées par l'extraction, la préparation et la séparation du minerai, y compris les matériaux résultant du traitement ou de l'épuration des eaux minières sont considérées comme des résidus miniers. Ainsi, la caractérisation géochimique des matériaux miniers du projet Shaakichiuwaanaan a été réalisée selon les critères énoncés dans ces documents.

Potentiel de génération d'acide

Selon le GCRMM, un résidu minier est considéré comme potentiellement générateur d'acide si sa teneur en soufre total est supérieure à 0,04 % et qu'au moins une des deux conditions suivantes est remplie :

- Un potentiel net de neutralisation (PNN) inférieur à 20 kg CaCO3/t ;
- Un ratio du potentiel de neutralisation (RPN) inférieur à 2.

Un résidu minier dont la teneur en soufre total est supérieure à 5 % est d'emblée considéré comme générateur d'acidité. Dans ce cas, l'initiateur du projet pourra choisir soit de considérer le matériel minier comme acidogène sans faire plus d'essais, soit de réaliser des essais cinétiques afin de vérifier son potentiel à générer de l'acidité.

Potentiel de lixiviation

Si la concentration en certains métaux dans un échantillon est supérieure au critère des sols A (équivalent à la teneur de fond pour le secteur à l'étude du Guide PSRTC (Beaulieu, 2021)), celui-ci doit être soumis aux essais de lixiviation selon les protocoles SPLP (lixiviation simulant les pluies acides) et CTEU-9 (lixiviation à l'eau).

Les résultats d'analyse des lixiviats et des fractions liquides des échantillons sont comparés aux critères suivants :

- Critères de qualité des eaux souterraines faisant résurgence dans les eaux de surface (critère RES, Annexe 7 du Guide PSRTC) ;
- Critères pour l'effluent final (Directive 019, Tableau 3-1) ;
- Critères pour les résidus miniers à risques élevés (GCRMM, Annexe A).

Pour qu'un résidu minier soit considéré comme non lixiviable, il faut que les concentrations en éléments métalliques dans le solide ne dépassent pas le critère A du Guide PSRTC ou que les lixiviats des essais SPLP et CTEU-9 montrent des concentrations en dessous des critères établis.

Pour qu'un résidu minier soit classé comme potentiellement lixiviable, deux conditions doivent être remplies : il faut qu'au moins un élément métallique soit présent dans la fraction solide à une teneur dépassant le critère A de l'Annexe 2 du Guide PSRTC et que ce même élément montre une concentration dans les lixiviats des essais SPLP et CTEU-9 supérieure au critère RES de l'Annexe 7 du Guide PSRTC.

Si ces conditions se vérifient pour un ou plusieurs éléments, des essais de lixiviation cinétiques peuvent être entrepris, tels que des essais de lixiviation en colonne ou des cellules de terrain pour vérifier le potentiel de lixiviabilité. Les concentrations dans les lixiviats de ces essais sont comparées aux mêmes critères que les lixiviats des essais statiques (SPLP et CTEU-9). Si l'initiateur du projet ne souhaite pas réaliser les essais cinétiques, les résidus peuvent être d'emblée classifiés comme lixiviables.

Résidus miniers à risques élevés (lixiviabilité)

Selon les critères du GCRMM, un matériau minier est considéré comme « à risques élevés » s'il produit, lors d'un essai TCLP, un lixiviat contenant un contaminant dont la concentration dépasse les critères de l'Annexe A du guide.

Radioactivité

Selon les critères de l'Annexe C du GCRMM, un résidu minier est considéré comme radioactif lorsqu'il émet des rayonnements ionisants (S) tels que le résultat de l'équation suivante, qui représente le calcul de la cote S, est supérieur à 1 :

S = C1/A1 + C2/A2 + C3/A3 + …Cn/An

où « C1, C2, C3, …Cn » représentent l'activité massique de ce résidu pour chaque radioélément qu'il contient, exprimée en kilobecquerels par kilogramme (kBq/kg)

et où « A1, A2, A3, …An » représentent, pour chaque radioélément qu'il contient, l'activité massique maximale mentionnée à l'Annexe 1 du Règlement sur les matières dangereuses. Celle-ci s'exprime en kilobecquerels par kilogramme (kBq/kg).

De la même façon, un résidu minier est considéré comme à risques élevés lorsqu'il est radioactif et son lixiviat d'essai TCLP émet des rayonnements ionisants (S), tels que le résultat de l'équation suivante, est supérieur à 0,05.

S = C1/A1 + C2/A2 + C3/A3 + …Cn/An

où « C1, C2, C3, …Cn » représentent l'activité volumique du lixiviat pour chaque radioélément qu'il contient, exprimée en kilobecquerels par litre (kBq/L)

et où « A1, A2, A3, …An » représentent, pour chaque radioélément qu'il contient, l'activité volumique décrite à l'Annexe 1 du Règlement sur les matières dangereuses. Cette activité est exprimée en kilobecquerels par litre (kBq/L).

4. Composition minéralogique

La composition minéralogique des matériaux miniers a été analysée sur des échantillons de carottes de forages réalisés entre 2021 et 2024. L'analyse a été réalisée sur les quatre lithologies de stériles : amphibolite, métasédiments (formation de Marbot), ultramafique et pegmatite ainsi que le minerai (pegmatite à spodumène). Ces lithologies ont été analysées à l'aide de deux technologies : la diffractométrie des rayons X (DRX) et la méthode TIMA (analyseur minéralogique automatisé de Tescan) basée sur l'imagerie réalisée au microscope électronique à balayage couplé à une analyse élémentaire en dispersion des rayons X.

L'analyse DRX a été réalisée sur 7 échantillons d'amphibolite, 2 échantillons d'ultramafiques, 1 échantillon de métasédiments, 90 échantillons de pegmatite et 456 échantillons de pegmatite à spodumène (minerai). Les résultats d'analyse sont résumés dans le **Tableau 4-1**.

Tableau 4-1 Composition minéralogique des différents matériaux miniers (méthode DRX)

(en % massique)	Amphibolite	Métasédiments (Marbot)	Ultramafique	Pegmatite	Pegmatite à spodumène (minerai)
Minéraux majeurs (> 10 %)	Plagioclase Amphiboles	Quartz Plagioclase	Phlogopite Amphiboles	Quartz Plagioclase	Quartz Plagioclase Spodumène
Minéraux mineurs (entre 1 et 10 %)	Quartz Microcline Chlorite Calcite Muscovite	Biotite Chlorite Muscovite Spodumène Feldspath K	Albite Muscovite Chlorite Magnétite Talc	Muscovite Microcline	Muscovite Microcline
Minéraux traces (< 1 %) ou sporadiques	Fluorite Magnétite	Tourmaline Magnétite Talc	Quartz Graphite	Spodumène Tourmaline Pollucite Beryl Chlorite Biotite Apatite	Tourmaline Pollucite Beryl Chlorite Biotite

L'amphibolite présente de l'hétérogénéité dans la composition minéralogique des différents échantillons. En général, elle montre une composition de plus de 50 % d'amphibolites, telle que l'actinolite et l'holmquistite et elle présente des teneurs en quartz variant entre 0,3 et 17,7 % massique avec une moyenne de 7 %. Les phases mineures sont la chlorite, la muscovite, le microcline et la calcite.

L'échantillon de métasédiments montre une composition de plus de 70 % de quartz et de plagioclase. Les phases mineures présentes sont la biotite, la chlorite, la muscovite, le spodumène et les feldspaths potassiques.

Les échantillons de roches ultramafiques sont composés à plus de 50 % de phlogopite et une proportion d'amphibole de l'ordre de 18 à 28 % massique. Les minéraux mineurs sont l'albite, la muscovite, la chlorite, la magnétite et le talc.

La pegmatite et la pegmatite à spodumène présentent des compositions minéralogiques relativement similaires, majoritairement composées de quartz et de plagioclase avec des minéraux mineurs, tels que la muscovite et le microcline. La principale différence est la teneur en spodumène, qui varie en moyenne de 24 % dans la pegmatite à spodumène et de 2,7 % dans la pegmatite considérée comme stérile.

La précision de la quantification DRX dépend étroitement de la qualité du modèle cristallographique et de la représentativité de l'échantillon analysé. Les méthodes d'interprétation des résultats permettent d'obtenir des proportions minéralogiques fiables, avec une incertitude de l'ordre de quelques pourcentages, lorsque les phases sont bien cristallisées. Cependant, la présence de phases amorphes, de textures préférentielles ou de chevauchements importants de pics peut réduire significativement la précision. Il est donc utile d'avoir recours à d'autres méthodes de quantification minéralogique afin d'obtenir plus de précision. De plus, l'analyse de la composition chimique des matériaux miniers a mis en évidence la présence d'arsenic, qui peut être problématique pour l'environnement.

Afin de vérifier la présence de minéraux potentiellement problématiques, une analyse minéralogique plus détaillée a été effectuée à l'aide de la méthode TIMA. Celle-ci permet d'identifier, de cartographier et de quantifier les minéraux présents sur la base de leur composition élémentaire. Cette méthode a été appliquée sur deux (2) échantillons d'amphibolite, trois (3) échantillons d'ultramafiques, un (1) échantillon de métasédiments (groupe de Guyer) et 13 échantillons de pegmatite à spodumène. Les résultats d'analyse sont résumés dans le **Tableau 4-2** pour les stériles et dans le **Tableau 4-3** pour le minerai. Les cases bleues indiquent les teneurs supérieures à 10 %. Les valeurs en gras indiquent des teneurs supérieures à 1 %. Les valeurs en gris indiquent des teneurs de moins de 0,1 %.

Il est à noter que l'analyse TIMA ne permet pas de distinguer les différents types de carbonates, étant donné que cette méthode quantifie les proportions élémentaires et que les carbonates possèdent des compositions élémentaires très similaires (C + O + métal). De plus, les éléments légers comme le carbone sont difficiles à quantifier par cette méthode, car leur production de rayons X est faible par rapport aux éléments plus lourds (Goldstein et al. 2018).

Minéraux sulfurés

Aucun sulfure n'a été mis en évidence dans les lithologies stériles par la méthode DRX, excepté pour la pegmatite, dont un échantillon sur 90 a montré une teneur de 0,3 % de pyrite. Pour ce qui est du minerai, la présence de sulfures est rare : sur les 456 échantillons analysés par cette méthode, seuls 1 à 3 échantillons ont montré la présence de pyrite, bornite, sphalérite et/ou stannite avec des teneurs maximales de l'ordre de 0,5 à 1,4 %. De la jarosite a également été mise en évidence dans deux échantillons de minerai.

La méthode TIMA a permis d'identifier les sulfures présents dans l'amphibolite et l'ultramafique. Deux des trois échantillons d'ultramafique présentent des teneurs de 0,75 et 1,75 % de pyrrhotite ($Fe_{1-x}S$). De faibles teneurs de l'ordre de 0,1 % de gersdorffite (NiAsS) et de chalcopyrite ($CuFeS_2$) ont également été observées. L'un des échantillons d'amphibolite n'a montré aucune présence de sulfures, alors que le second a présenté une teneur en pyrrhotite de 1,77 %. L'échantillon de métasédiments a montré une teneur de 2,4 % de pyrrhotite et 0,18 % d'arsénopyrite (FeAsS). Dans la pegmatite à spodumène, aucune concentration significative en sulfure n'a été identifiée.

Il est à noter que les échantillons sélectionnés pour l'analyse TIMA sont ceux qui ont été utilisés pour les essais cinétiques en cellules humides. Certains d'entre eux ont été sélectionnés spécifiquement pour leur teneur élevée en sulfures. L'analyse TIMA permet d'identifier la nature des sulfures présents. Toutefois, au vu du faible nombre d'échantillons analysés par cette méthode, les quantifications obtenues ne peuvent être rapportées à l'ensemble de chaque lithologie. La distribution des teneurs en sulfures dans l'ensemble des échantillons prélevés dans chaque lithologie doit également être prise en compte.

Minéraux neutralisants

Certains minéraux ont la capacité de neutraliser l'acidité générée par l'oxydation des sulfures, tels que les carbonates et, dans une moindre mesure les plagioclases calciques. L'analyse par DRX a mis en évidence les minéraux suivants :

- Amphibolite : Présence de calcite dans cinq des sept échantillons d'amphibolite à des teneurs comprises entre 0,3 et 5,6 %. Les deux autres échantillons présentent des teneurs de 0 et 36,7 % de calcite. Le deuxième carbonate présent est l'ankérite identifiée dans deux des échantillons à des teneurs de 1,9 et 20,3 %.
- Métasédiments et ultramafique : Aucun carbonate n'a été identifié dans les échantillons de ces lithologies.
- Pegmatite : Deux échantillons de pegmatite ont montré des teneurs en carbonates de 0,427 % (minéral non identifié) pour l'un et de 6,8 % (dolomite) pour le second.
- Pegmatite à spodumène : Les carbonates identifiés sont la calcite et l'ankérite. Ils sont toutefois présents dans une minorité d'échantillons et à des teneurs très faibles (<0,05 %). Du fait de l'imprécision de la quantification par DRX. La présence de ces carbonates est incertaine.

Les résultats de quantification par la méthode TIMA confirment la présence de carbonates dans les lithologies stériles avec des teneurs comprises entre 0,4 % et 10,6 % pour les échantillons ultramafiques, entre 0,3 et 0,8 % pour l'amphibolite et de 1,1 % pour l'échantillon de métasédiments. Ces résultats confirment également que la teneur en calcite est très faible dans la pegmatite à spodumène avec une moyenne de 0,06 %.

Minéraux potentiellement problématiques

La présence de minéraux porteurs d'arsenic et de nickel a été mise en évidence par la méthode TIMA. Les échantillons d'ultramafiques montrent la présence de faibles quantités (<0,2 %) de nickéline (NiAs), de gersdorffite (NiAsS) et de pentlandite ($(Fe,Ni)_9S_8$). Les échantillons d'amphibolite présentent des teneurs traces en nickéline, gersdorffite de l'ordre de 0,02 %-0,03 %. L'échantillon de métasédiments présente une teneur de 0,18 % d'arsénopyrite (FeAsS). Les échantillons de pegmatite à spodumène contiennent de faibles quantités d'apatite, de fluorite et de phosphates de lithium. Ces échantillons montrent également une teneur moyenne de 0,47 % de pétalite ($LiAlSi_4O_{10}$). L'oxydation ou la dissolution de ces minéraux pourraient libérer des éléments chimiques (arsenic, nickel, lithium, phosphore, fluor) dans l'eau de contact avec ces matériaux et générer un impact potentiel.

5. Granulométrie

La granulométrie des échantillons joue un rôle déterminant dans la réactivité des minéraux et influence directement leurs propriétés géochimiques environnementales. La littérature scientifique montre que les fractions fines présentent généralement une réactivité plus élevée, en raison de leur surface spécifique accrue, ce qui favorise la libération d'éléments chimiques lors des processus de dissolution et d'altération. Les données disponibles sur la granulométrie des échantillons caractérisés sont décrites dans les sections suivantes.

Telle que décrite à la **Figure 5-1**, la taille de particules attendue pour les stériles extraits lors de l'exploitation est principalement comprise entre 1 cm et 1 m (Vision Geochemistry, 2025). Toutefois, dans la présente étude, les essais de lixiviation ont été réalisés sur des échantillons de carottes de forages concassés. Pour les essais en cellules humides, la granulométrie de l'échantillon a été réduite à moins de 6,3 mm. Pour les essais en colonne de l'UQAT, la taille de particule est comprise entre 0,35 et 20 mm selon l'évaluation par tamisage (**Figure 5-1**). Des essais de granulométrie laser ont également été réalisés sur la fraction fine non évaluée par tamisage. Ils ont mis en évidence des particules de taille allant jusqu'à 0,001 mm.

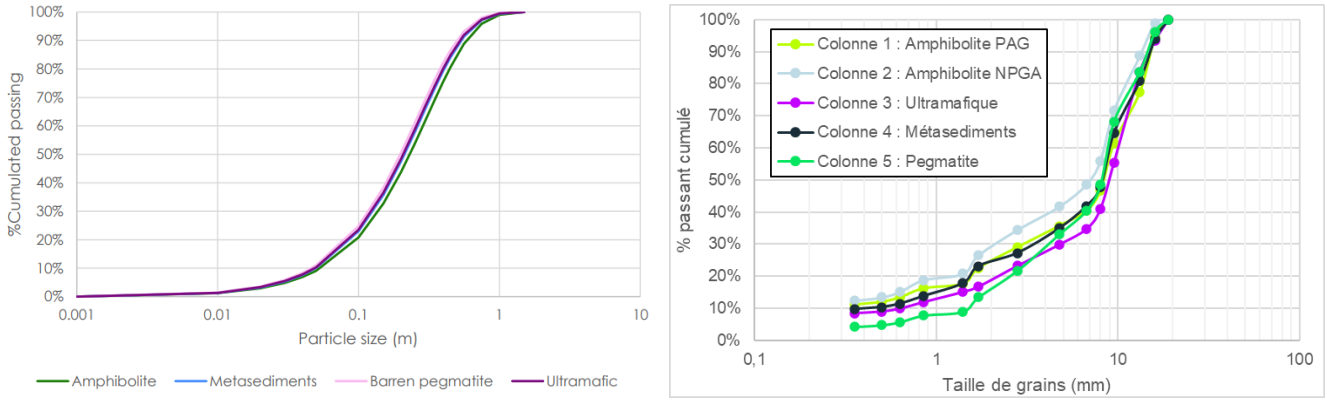

Figure 5-1 Granulométrie attendue pour les lithologies stériles du projet (à gauche, tirée de Vision Geochemistry, 2025) et granulométrie des échantillons mis à l'essai dans les colonnes UQAT (à droite)

La granulométrie des résidus miniers qui ont été produits lors des essais métallurgiques est présentée à la **Figure 5-2** (AtkinsRéalis, 2025). L'échantillon analysé est un composite des différents flux de résidus de procédés qui seront générés dans les proportions projetées lors de l'exploitation. Sa granulométrie est principalement celle d'un sable graveleux.

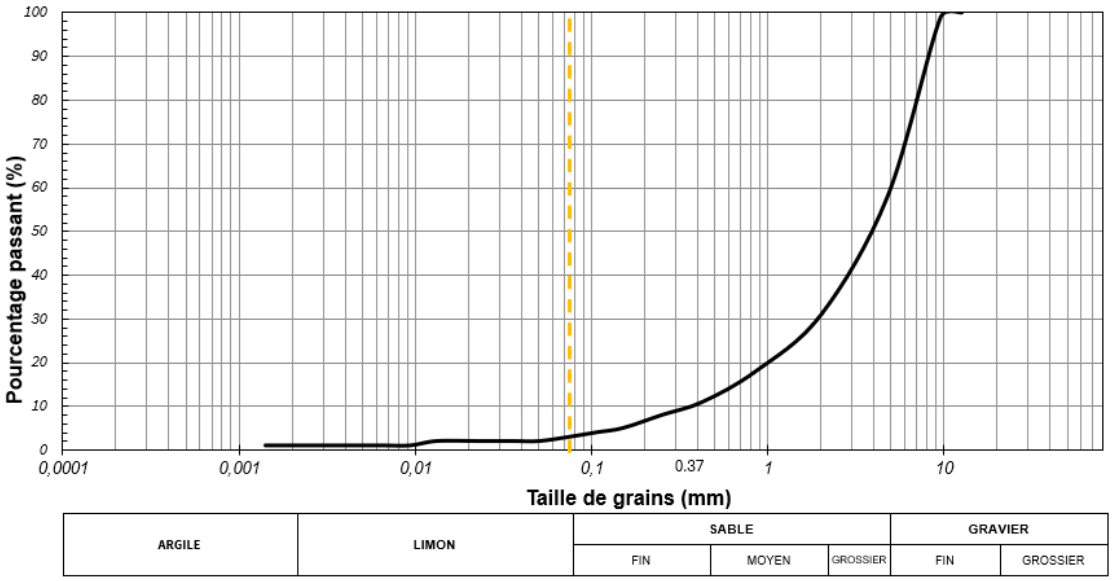

Figure 5-2 Granulométrie des résidus miniers produits par les essais métallurgiques (AtkinsRéalis, 2025)

6. Classification des matériaux miniers

L'ensemble des analyses géochimiques effectuées sur les matériaux miniers du projet ne sera pas présenté dans cette section. Comme mentionné en introduction, la majorité de ces résultats ont été détaillés dans une étude antérieure (Vision Geochemistry, 2025). Il est donc possible de se référer à cette étude pour visualiser les résultats complémentaires qui ont permis de classifier les matériaux miniers dans cette note technique. Les deux principaux facteurs de classification sont le potentiel de génération d'acide, et le potentiel de lixiviabilité. Les deux prochaines sections traiteront ainsi de ces facteurs, pour classifier les matériaux miniers du projet.

6.1 Potentiel de génération d'acide

6.1.1 Distribution du soufre et du carbone et représentativité des essais

La génération d'acidité dans un matériau est liée à l'oxydation des sulfures présents dans les échantillons. La teneur en soufre sous forme de sulfure permet d'évaluer de façon préliminaire le potentiel d'acidification. La teneur en carbone total permet de façon préliminaire d'évaluer la présence de minéraux neutralisants. La **Figure 6-1** et la Figure 6-2 présentent les distributions des teneurs en ces deux éléments sur les 350 échantillons analysés, répartis par lithologie. Il est observé que les teneurs en sulfures sont généralement faibles, en particulier dans l'ultramafique, la pegmatite, la pegmatite à spodumène et les résidus miniers qui sont générés à partir de cette dernière. Les teneurs en sulfures les plus importantes sont observées dans les métasédiments avec 75 % des teneurs comprises entre 0 et 0,43 % et 95 % des valeurs comprises entre 0 et 1 %.

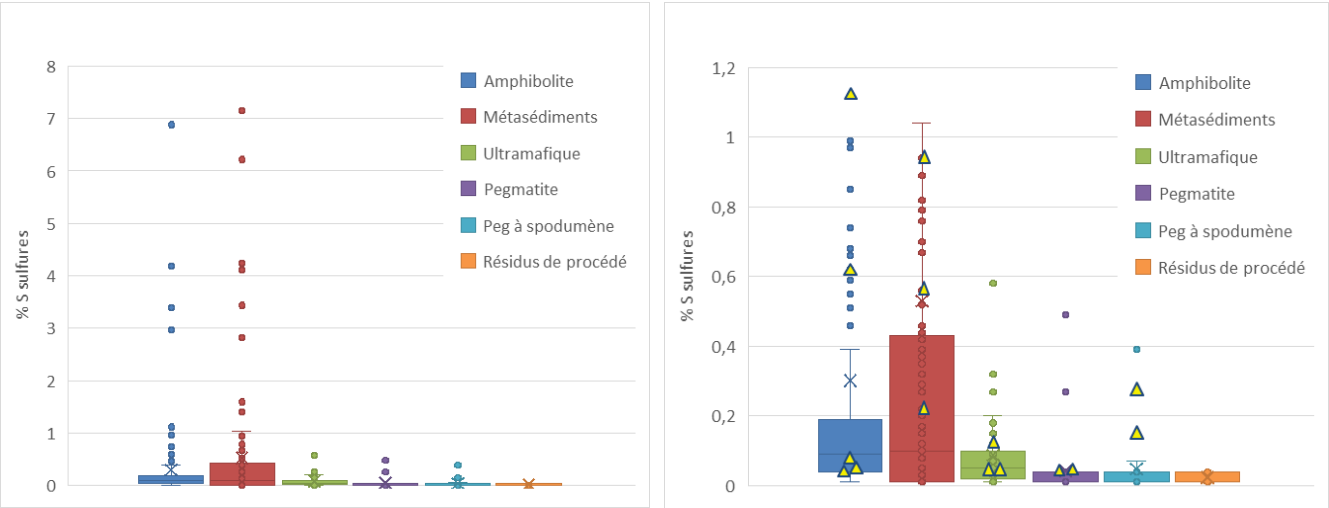

Figure 6-1 Distribution des teneurs en soufre sous forme de sulfures (vue d'ensemble à gauche et vue détaillée à droite)

Sur le graphique de droite de la **Figure 6-1**, les triangles indiquent les teneurs en soufre sous forme de sulfures des échantillons qui ont été utilisés pour les essais en cellules humides et les essais de lixiviation en colonne. Il est constaté que les échantillons sélectionnés pour ces essais couvrent adéquatement l'intervalle des concentrations mesurées lors des essais statiques pour l'amphibolite, l'ultramafique et la pegmatite. Pour les métasédiments, les trois échantillons sélectionnés ont une concentration en soufre sous forme de sulfures supérieure à la médiane des concentrations mesurées pour cette lithologie. Cette sélection permet d'évaluer le potentiel de génération d'acidité de la lithologie de façon conservatrice. Pour la pegmatite à spodumène, les échantillons sélectionnés présentent des concentrations considérablement plus élevées que celles observées dans l'ensemble de la lithologie. Elles ne sont pas représentatives des teneurs observées dans le minerai. L'objectif de ces deux essais est de vérifier le comportement de cette lithologie dans le cas de la présence locale de sulfures.

Pour ce qui est de la teneur en carbone total, les teneurs sont généralement faibles sur l'ensemble des matériaux miniers caractérisés. Les résultats confirment que les carbonates sont quasi absents de la pegmatite, de la pegmatite à spodumène et des résidus miniers. La lithologie ultramafique présente la plus grande teneur avec 95 % des teneurs comprises entre 0,01 % et 0,75 %.

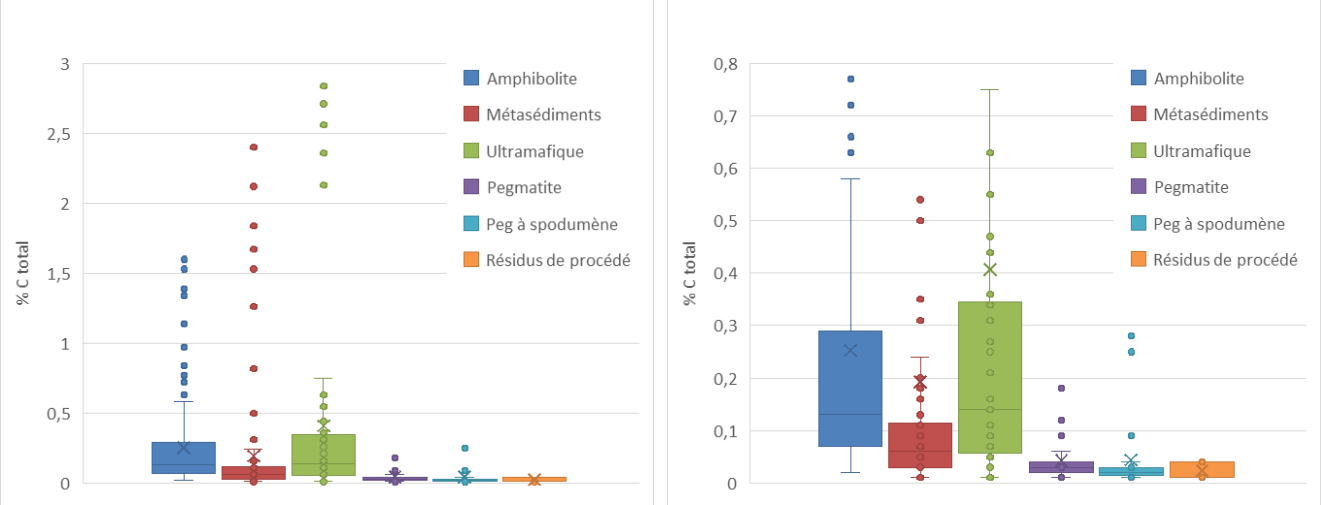

Figure 6-2 Distribution des teneurs en carbone total (vue d'ensemble à gauche et vue détaillée à droite)

6.1.2 Essais statiques

Les résultats des essais de détermination du potentiel de génération d'acide réalisés sur 350 échantillons de matériaux miniers sont fournis dans l'étude de caractérisation effectuée par Vision Geochemistry en 2025. Ces essais ont été réalisés sur les cinq lithologies du projet, ainsi que sur les résidus miniers.

Le **Tableau 6-1** présente un sommaire des résultats obtenus. Il contient les teneurs médianes en soufre pour chaque lithologie, le nombre d'échantillons interprétés comme non potentiellement générateurs d'acidité (NPGA) ou potentiellement générateurs d'acidité (PGA) selon les critères du GCRMM, ainsi que le ratio du potentiel de

neutralisation (RPN) calculé par le rapport de la médiane du potentiel de neutralisation (PN) des échantillons de la lithologie concernée sur la médiane des potentiels d'acidification (PA) de ces mêmes échantillons.

Tableau 6-1 Sommaire des résultats des essais de détermination du potentiel de génération d'acide

Lithologies	Nombre d'échantillons total	% de soufre total (médiane)	Nombre d'échantillons NPGA	Nombre d'échantillons PGA	RPN global
Amphibolite	128	0,14	112	16	5,3
Ultramafique	54	0,07	51	3	8,8
Métasédiments	101	0,18	65	36	2,4
Pegmatite	33	0,01	31	1	31,5
Pegmatite à spodumène	25	0,01	24	1	14,0
Résidus miniers	9	0,02	9	0	15,7

Pour la lithologie ultramafique, le nombre d'échantillons considéré comme PGA est faible en comparaison du nombre d'échantillons analysés et le RPN global de la lithologie est nettement supérieur à 2 (RPN global de 8,8). Il est également à noter que le PN de la lithologie ultramafique est sous forme de carbonate (**Figure 6-3**) qui est le minéral le plus efficace en termes de vitesse de réaction pour la neutralisation. Il est donc peu probable que cette lithologie soit acidogène.

Le nombre d'échantillons d'amphibolite PGA est relativement faible en comparaison au nombre d'échantillons analysés dans cette lithologie et son RPN global est de 5,3. Pour les métasédiments, le nombre d'échantillons PGA est proportionnellement plus élevé que pour l'ultramafique et l'amphibolite, et son RPN global est de 2,4. Pour ces deux lithologies stériles, les teneurs en carbonates sont plus faibles que dans la lithologie ultramafique, en particulier dans les métasédiments, et le PN semble provenir des carbonates ainsi que des silicates. Les silicates sont moins efficaces pour neutraliser l'acidité du fait d'une cinétique de réaction plus lente. La teneur en sulfures dans l'amphibolite étant généralement faible avec une teneur médiane de 0,07 %, il est toutefois probable que cette lithologie soit NPGA. Le potentiel de génération d'acide des métasédiments est plus incertain, car cette lithologie présente le RPN global le plus faible.

Les essais cinétiques ont été réalisés afin de pouvoir confirmer la classification de ces trois lithologies de stériles.

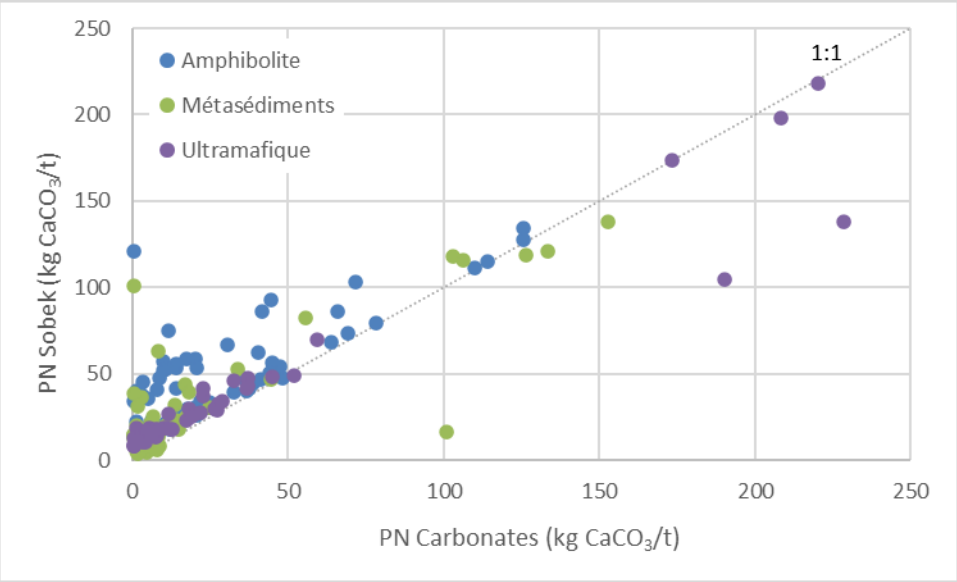

Figure 6-3 Comparaison du PN évalué sur la base de la teneur en carbonates et du PN Sobek modifié

6.1.3 Essais cinétiques

6.1.3.1 Essais en cellules humides

Des essais en cellules humides ont été réalisés sur les différents matériaux miniers du projet sur une période de deux années (Vision Geochemistry, 2025). Les résultats d'analyse des lixiviats des cellules ont montré des pH légèrement alcalins au début des essais avec des valeurs comprises entre 7,5 et 9. Puis ces valeurs ont progressivement baissé jusqu'à 60 semaines d'essais où elles se sont stabilisées entre 6 et 7,5 (**Figure 6-4**). Quelques valeurs légèrement en dessous de 6 ont été mesurées vers la fin de l'essai pour les cellules CV5-WR-HCT-59 (ultramafique) et -HCT-39 (métasédiments).

Les résultats indiquent que seules trois cellules (sur 15 au total) montrent une génération d'acidité qui reste toutefois de faible ampleur. Le lixiviat de l'échantillon d'amphibolite dans la cellule HCT-2 montre une faible acidité à court terme qui culmine à une valeur de 10 mg/L à 15 semaines d'essai, puis passe en dessous de la limite de détection pour le reste de la durée de l'essai (**Figure 6-5**).Le lixiviat de l'échantillon de métasédiments dans la cellule HCT-50 montre une acidité de concentration variable qui augmente à 18 mg/L à la 60^{e} semaine de l'essai, puis redescend progressivement à 4 mg/L à la fin de celui-ci. Les concentrations en sulfates augmentent de 10 à 20 mg/L en fin d'essai (**Figure 6-6**) et la teneur en fer passe de 0,02 à 0,6 mg/L entre la 60^{e} semaine de l'essai et la fin de celui-ci. Il est toutefois à mentionner que l'essai en cellule humide tend à favoriser le développement de conditions légèrement acides (pH 6) même pour des échantillons qui ne sont pas acidogènes du fait du pH relativement acide de l'eau déionisée et du rapport liquide sur solide élevé lors des rinçages. Le lixiviat de l'échantillon d'ultramafique dans la cellule HCT-59 montre une acidification moins marquée que l'échantillon de métasédiments HCT-50. L'acidité varie entre 2 et 9 mg/L tout au long de l'essai avec des valeurs légèrement plus élevées en fin d'essai (7-9 mg/L). Les essais en cellule humide confirment que les échantillons de pegmatite, de pegmatite à spodumène et de résidus miniers sont non acidogènes.

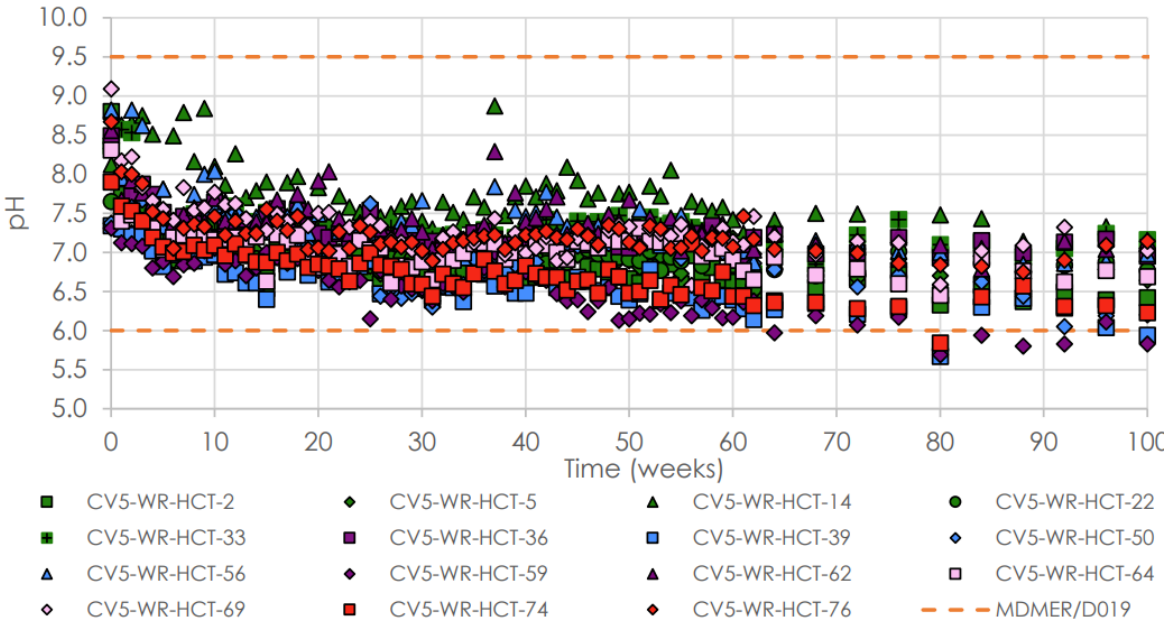

Figure 6-4 Évolution du pH dans les lixiviats des cellules humides (Vision Geochemistry, 2025)

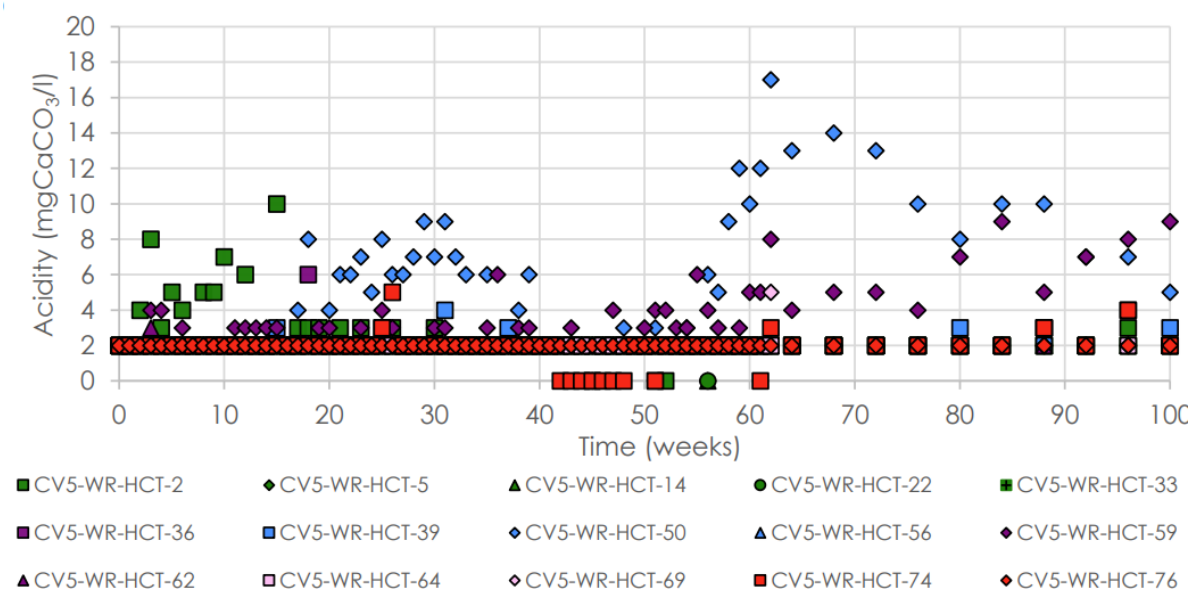

Figure 6-5 Évolution de l'acidité dans les lixiviats des cellules humides (Vision Geochemistry, 2025)

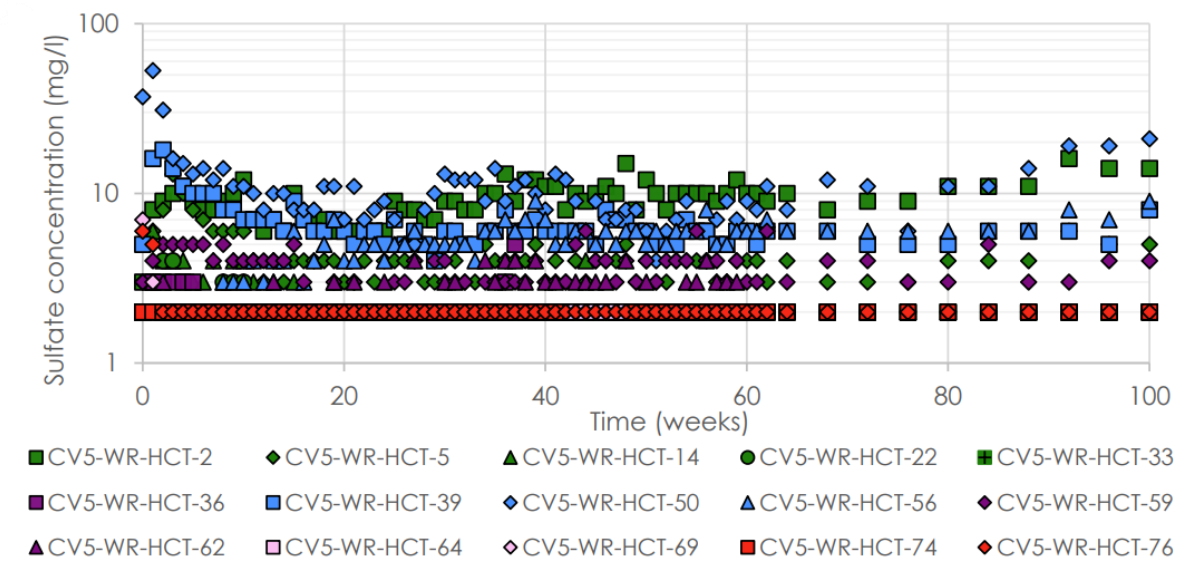

Figure 6-6 Évolution de la concentration en sulfates dans les lixiviats des cellules humides (Vision Geochemistry, 2025)

6.1.3.2 Essais en colonnes (UQAT)

Les essais en colonne sur les lithologies stériles ont été menés sur 336 jours. Les graphiques des résultats sont disponibles en **Annexe A**. Les résultats d'analyses des lixiviats en ce qui concerne le potentiel de génération d'acide sont les suivants :

- Pour toutes les lithologies, le pH passe de légèrement alcalin à autour de la neutralité en fin d'essai.
- L'acidité des lixiviats reste proche de la limite de détection (2-4 mg/L) tout au long des essais pour toutes les lithologies, ce qui signifie que, si de l'acidité est générée, la disponibilité des minéraux neutralisants est suffisante pour neutraliser l'acidité générée durant les 336 jours des essais.
- La concentration en sulfates est plus élevée dans les lixiviats de la colonne drainée de métasédiments (colonne C4) que pour les autres lithologies, indiquant qu'un phénomène d'oxydation des sulfures se produit. Cet argument est soutenu par le fait que les teneurs en sulfates dans les lixiviats de la colonne de métasédiments en conditions submergées (colonne C7) sont significativement inférieures à celles de la colonne C4. Les concentrations en soufre (sulfates) dans les lixiviats de la colonne C4 passe de 78 mg/L en début d'essai à 46 mg/L en fin d'essai alors que ceux de la colonne C7 submergée passe de 40 mg/L à 13 mg/L. La présence de l'eau limite la diffusion de l'oxygène vers les sulfures et donc leur oxydation. Pour les autres lithologies, la teneur en sulfates se maintient en dessous de 10 mg/L, ce qui semble indiquer une faible réactivité.

Les courbes de neutralisation/oxydation (Benzaazoua et al. 2004) ont été tracées pour les trois lithologies (ultramafique, amphibolite et métasédiments). Elles sont présentées à la **Figure 6-7**. Celles-ci permettent de comparer le taux de génération des charges cumulées normalisées en soufre (marqueur de l'oxydation) avec les charges cumulées normalisées de calcium, magnésium et manganèse (marqueurs de la neutralisation). Une relation linéaire est obtenue pour chaque lithologie et la pente de la droite est spécifique à chaque lithologie. Dans l'hypothèse où ce taux de réaction se maintiendrait dans le temps, il serait possible de vérifier, de façon théorique, pour chaque lithologie, lesquels des minéraux acidogènes ou neutralisants s'épuiseraient en premier, par

extrapolation. Lorsque la concentration moyenne initiale en soufre et la somme des concentrations moyennes en calcium, magnésium et manganèse sont comparées aux courbes extrapolées pour chaque lithologie, il est constaté que ces points sont localisés au-dessus de leur courbe respective. Selon cette interprétation, les sulfures seraient théoriquement épuisés avant les minéraux neutralisants. Par conséquent, les trois lithologies seraient considérées comme non acidogènes.

Cette méthode d'interprétation repose toutefois sur plusieurs hypothèses, dont celle selon laquelle la composition minéralogique serait homogène dans chaque lithologie, et celle selon laquelle la réactivité des minéraux resterait constante au cours du temps. Afin de consolider cette interprétation, des essais à plus grande échelle seraient requis afin de s'assurer de bien capter la variabilité au sein de chaque lithologie.

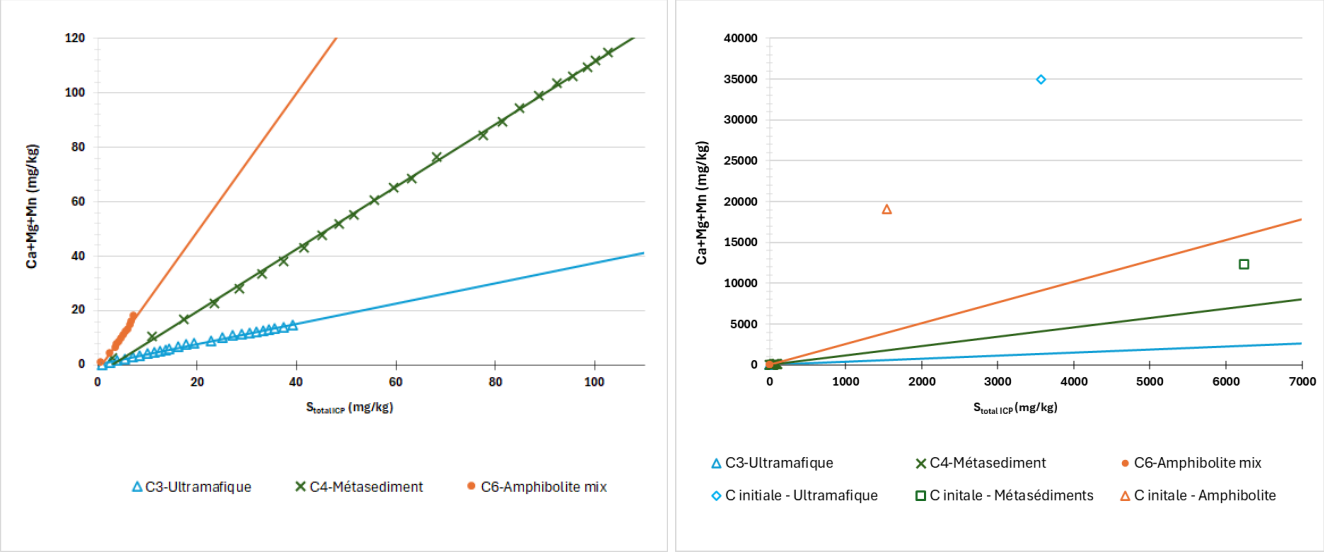

Figure 6-7 Courbes d'oxydation/neutralisation pour les lithologies ultramafique, métasédiments et amphibolite (à gauche) et leur extrapolation (à droite)

6.2 Potentiel de lixiviabilité

6.2.1 Distribution de l'arsenic et représentativité des essais

Sur la base des résultats des essais de lixiviation statiques (SPLP et CTEU9), l'arsenic est l'un des éléments d'intérêt quant à la lixiviabilité des matériaux miniers du projet. La **Figure 6-8** présente la distribution des teneurs en arsenic extractible des 350 échantillons analysés, répartis par lithologie. Il est observé que la teneur en arsenic est considérablement plus élevée dans la lithologie ultramafique que dans les autres lithologies avec une médiane de 210 ppm. Les autres lithologies montrent des médianes comprises en 10 et 16 ppm. Les résidus miniers présentent une médiane de 51 ppm.

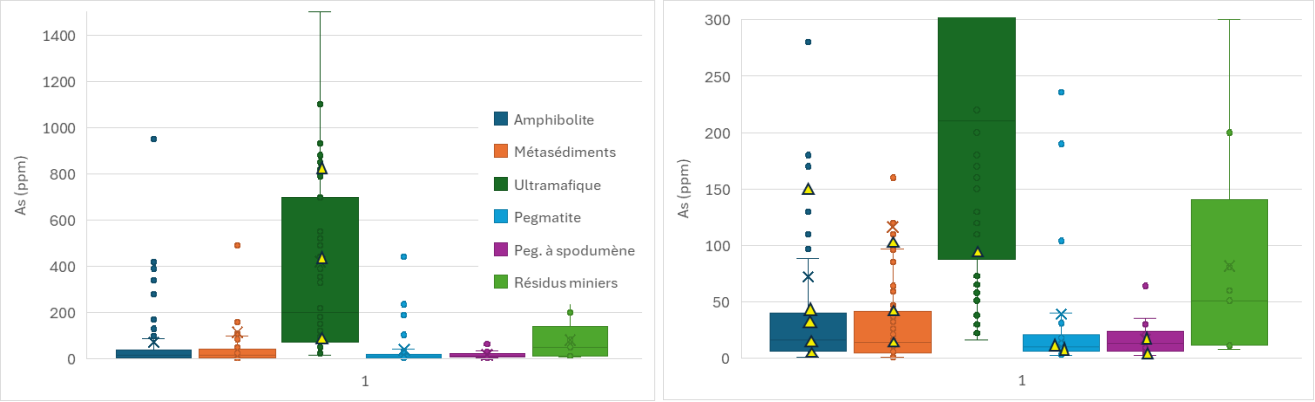

Figure 6-8 Distribution des teneurs en arsenic extractible (vue d'ensemble à gauche et vue détaillée à droite)

Sur les graphiques de la **Figure 6-8**, les triangles indiquent les teneurs en arsenic extractible des échantillons qui ont été utilisés pour les essais en cellules humides et les essais de lixiviation en colonne. Il est constaté que les échantillons sélectionnés pour ces essais couvrent adéquatement l'intervalle des concentrations mesurées lors des essais statiques pour chaque lithologie.

6.2.2 Essais de lixiviation statiques

Les données de teneurs en métaux extractibles et d'analyse des lixiviats des essais SPLP et CTEU-9 disponibles pour chaque matériau (Vision Geochemistry 2025) ont été réinterprétés par rapport aux critères du GCRMM afin de déterminer le potentiel de lixiviabilité de chacun d'eux. Le **Tableau 6-2** récapitule l'ensemble des résultats de la démarche de classification.

La lixiviabilité en métaux varie selon les lithologies, tant en nombre de dépassements des critères de classification qu'en type d'éléments chimiques. Une tendance générale se dégage toutefois : la lixiviation potentielle de l'arsenic apparaît comme un phénomène relativement commun dans toutes les lithologies évaluées, ainsi que dans les résidus miniers. D'autres éléments présentent également des dépassements de critères applicables (critère A et critère RES), c'est notamment le cas du cuivre (27 % des échantillons d'amphibolite, 12 % des échantillons des métasédiments, 17 % de la lithologie ultramafique ou encore 44 % des résidus miniers), ainsi que le chrome pour 78 % des échantillons appartenant à la lithologie ultramafique. D'autres dépassements plus sporadiques ont aussi été observés pour certains éléments, incluant l'argent, le cadmium, le plomb, le zinc et le nickel.

Pour l'interprétation des résultats des essais de lixiviation, il est requis de considérer non seulement la présence de dépassements des critères, mais aussi l'ampleur des écarts par rapport aux critères applicables. En ce qui concerne le Critère A, seuls l'arsenic et le nickel dépassent ce seuil d'un ordre de grandeur dans plusieurs échantillons provenant des lithologies amphibiotique, métasédimentaire et ultramafique. La lithologie ultramafique se distingue particulièrement : 30 % de ses échantillons présentent des dépassements en arsenic de deux ordres de grandeur par rapport au critère, et un échantillon dépasse même ce critère de trois (3) ordres de grandeur. Ces résultats soulignent un potentiel important de lixiviation de l'arsenic, surtout pour les unités ultramafiques.

Les résultats des essais de lixiviation CTEU-9 indiquent une mobilisation potentielle de l'arsenic dans les conditions des essais. En effet, 19 % des échantillons ultramafiques dépassent le critère RES pour l'arsenic de deux (2) ordres de grandeur, et 56 % d'un ordre de grandeur. Un total de 22 % des résidus miniers et de 8 % de la pegmatite (minerai) dépassent également d'un ordre de grandeur le critère RES pour ce métal. De plus, les résultats de ces essais montrent des dépassements de critères d'un ordre de grandeur pour plusieurs autres éléments. C'est notamment le cas de l'argent (22 % des échantillons de résidus miniers et 2 % pour les métasédiments), le chrome (7 % de la lithologie ultramafique), le cuivre (3 % des métasédiments et 6 % de la pegmatite stérile), le lithium (12 % de la pegmatite à spodumène), l'antimoine (22 % de l'ultramafique et 8 % de la pegmatite à spodumène) et le thorium (12 % de la pegmatite stérile, et 8 % de la pegmatite à spodumène).

En comparaison, les essais SPLP montrent un nombre plus limité de dépassements. Aucun dépassement ne dépasse un ordre de grandeur par rapport au critère, sauf pour l'argent, et ce, seulement dans quelques échantillons. Ces résultats suggèrent une lixiviabilité plus faible dans les conditions simulées par les essais SPLP, par rapport à celles représentées par les essais CTEU-9. Les essais CTEU-9 simulent des conditions plus rigoureuses que les essais SPLP du fait de pulvérisation de l'échantillon à -150 microns (-9,5 mm pour l'essai SPLP), un temps d'agitation de 7 jours (18 h pour l'essai SPLP) et un rapport de mélange liquide/solide cinq fois plus faible que celui du SPLP. L'objectif de cet essai n'est pas de reproduire les conditions d'altération du site, mais d'identifier les éléments chimiques d'intérêt dont la lixiviabilité doit être examinée plus en détail.

Tableau 6-2 Interprétation du potentiel de lixiviabilité des matériaux miniers

Lithologies	Métaux > Critère A [1]	SPLP >RES[2]	CTEU-9>RES[2]	Métaux>Critère A et lix>RES [3]	Classification préliminaire
Amphibolite n = 128	As (98), Cu (98), Ni (36), Cr (9), Sn (7), Co (3), Cd (2), Pb (2), Zn (2), Ag (1), Ba (1), Hg (1)	Zn (5), Ag (3), Cu (3), As (2)	Li (69), Cu (37), As (26), Sb (20), Ag (16), Cr (7) Cd (1), Pb (1), Th (1), V (1)	**Cu (35)**, **As (26)**, Ag (1), Cd (1), Cr (1)	Potentiellement lixiviable en cuivre et en arsenic
Métasédiments n = 101	As (70), Cu (18), Ni (12), Sn (12), Cr (8), Zn (6), Cd (5), Ag (3), Pb (3), Co (2), Mn (2), Ba (1), Hg (1)	Cu (4), Ag (2), Zn (2), As (1), Sb (1)	Li (63), Cu (34), Ag (21), As (16), Sb (9), Cr (5), Pb (5), Zn (3), Cd (2), V (2), Be (1), Mn (1), Th (1)	**As (16)**, **Cu (12)**, Cr (5), Ag (2), Pb (2), Zn (2), Cd (1)	Potentiellement lixiviable en arsenic et en cuivre
Ultramafique n = 54	As (54), Cr (53), Ni (53), Co (35), Cu (24), Sn (5), Ag (1), Cd (1), Mo (1), Pb (1), Zn (1)	As (17), Sb (1)	As (50), Cr (42), Sb (36), Li (21), Cu (13), Ni (8), Ag (7)	**As (50)**, **Cr (42)**, **Cu (9)**, **Ni (8)**, Ag (1)	Potentiellement lixiviable en arsenic, chrome, cuivre et nickel
Pegmatite à spodumène n = 25	As (22), Sn (4), Cr (3), Ag (1)	Cu (3), Ag (2), Be (2), Zn (2)	Li (25), As (19), Th (19), Sb (10), Ag (7), Be (7), Cu (6)	**As (18)**	Potentiellement lixiviable en arsenic
Pegmatite stérile n = 33	As (25, Cr (4), Cu (3), Sn (3), Ni (1), Pb (1)	Be (4), Cu (4), Ag (3), Zn (3), Pb (1)	As (24), Th (21), Cu (19), Be (13), Li (8), Ag (6), Pb (3), Fe (2), Sb (2), Cr (1), V (1), Zn (1)	**As (24)**, Cu (3), Pb (1)	Potentiellement lixiviable en arsenic
Résidus miniers n = 9	As (9), Cr (5), Ni (3)	Cu (3), Ag (2), Zn (2)	As (9), Th (6), Li (5), Sb (5), Cr (4), Cu (5), Ag (4), Zn (2), Th (1)	**As (9)**, **Cr (4)**	Potentiellement lixiviable en arsenic et en chrome

Notes :

1. *Il n'y a pas de critère A pour le lithium, l'antimoine et le thorium, entre autres. Ils ont toutefois été intégrés dans l'analyse comme étant des éléments chimiques d'intérêt.*
2. *Plusieurs éléments chimiques d'intérêt n'ont pas de critère RES. Les critères CVAA (critères de vie aquatique - effet aigu) ont été utilisés à titre indicatif. C'est le cas du béryllium, du chrome, du cobalt, de l'étain, du fer, du lithium, du thorium et du vanadium.*
3. *Comme mentionné dans la Section 3.0, pour qu'un échantillon soit considéré comme potentiellement lixiviable, les résultats des essais doivent démontrer à la fois un dépassement du critère A pour les métaux extractibles, et du critère RES pour les essais SPLP ou CTEU-9 et cela pour le même élément chimique dans le même échantillon.*

6.2.3 Essais de lixiviation cinétiques

Entre 2024 et 2025, des essais de lixiviation en colonnes sur les différentes lithologies stériles du projet (UQAT) et sur les résidus miniers (Vision Geochemistry, 2025) ont été réalisés afin de permettre une meilleure compréhension de la lixiviabilité en métaux de ces matériaux. Les résultats de ces essais sont présentés en **Annexe A**.

6.2.3.1 Lixiviabilité des lithologies stériles

Comme décrit dans la **Section 2.2**, des essais de lixiviation en colonne ont été effectués par l'UQAT sur l'ensemble des lithologies stériles pendant un an. Les résultats des essais sont résumés ci-dessous.

- Arsenic : des dépassements des critères D019 et RES sont observés pour l'ensemble des lithologies. Ces concentrations diminuent au cours des essais pour les échantillons de pegmatite et de métasédiments devenant inférieures au critère de la D019 après 200 et 100 jours d'essais respectivement. Pour les échantillons d'amphibolite et d'ultramafique, les concentrations se maintiennent au-dessus du critère RES sur les 300 jours des essais et, à titre indicatif, jusqu'à 250 jours d'essais, les concentrations en arsenic dans les échantillons d'ultramafique sont supérieures au critère de l'Annexe A du GCRMM définissant les résidus miniers à risques élevés. Les concentrations baissent légèrement vers la fin de l'essai, mais elles restent proches de ce critère jusqu'à la fin des essais. Jusqu'à 250 jours des essais, la concentration en arsenic dans la colonne d'ultramafique en conditions submergées présentent des concentrations en arsenic supérieures à celles observées dans la colonne d'ultramafique en conditions drainées. Ce phénomène semble indiquer la présence de minéraux porteurs d'arsenic qui présentent une certaine solubilité dans l'eau.
- Cadmium : Les concentrations en cadmium sont relativement stables et supérieures au critère RES pour chaque lithologie tout au long des essais, excepté pour la pegmatite et les métasédiments. Jusqu'à 70 jours d'essai, les concentrations sont supérieures au critère pour la pegmatite, puis elles baissent sous celui-ci. Pour les deux colonnes de métasédiments, les concentrations se maintiennent en dessous du critère tout au long de l'essai. Il est à noter que les concentrations en cadmium dans les lixiviats des essais en cellules humides étaient toujours proches ou égales à la limite de détection pour toutes les lithologies mises à l'essai.
- Cuivre : Les résultats montrent des concentrations relativement stables tout au long des essais, avec des concentrations généralement inférieures aux critères RES pour toutes les lithologies, excepté la pegmatite qui montre dans son lixiviat des concentrations supérieures au critère durant les 50 premiers jours des essais.
- Nickel : Les concentrations demeurent inférieures aux critères réglementaires pour l'ensemble des lithologies tout au long des essais, à l'exception de l'amphibolite en conditions submergées, qui présente quelques dépassements des critères RES/D019 en début d'essai. Cependant, après 200 jours d'essai, les concentrations chutent et restent sous les critères.
- Antimoine : Les deux colonnes d'ultramafique montrent des concentrations supérieures au critère RES pour toute la durée de l'essai. La colonne C9 (mélange de toutes les lithologies stériles) montre des concentrations supérieures au critère dans les premiers 150 jours de l'essai, probablement du fait de sa composante en ultramafique.
- Lithium, plomb, uranium, zinc : Les concentrations se maintiennent sous les critères RES (CVAA pour le lithium, à titre indicatif) pour toutes les lithologies sur toute la durée des essais.

6.2.3.2 Lixiviabilité du minerai

Deux essais en cellules humides, CV-WR-HCT-74 et -76, ont été réalisés sur le minerai (Vision Geochemistry, 2025). Les résultats de ces essais sont présentés en **Annexe A** pour les principaux éléments d'intérêt. Les résultats des essais ont mis en évidence dans les lixiviats de l'un de ces échantillons (HCT- 74) des concentrations en arsenic supérieures au critère RES pour les trois premiers rinçages et des concentrations en lithium égales au critère CVAA (Critère de vie aquatique – effet aigu) pour les deux premiers rinçages. Par la suite, les concentrations en ces deux éléments s'amenuisent progressivement dans les lixiviats. L'échantillon de la cellule HCT-76 ne montre pas de concentrations en arsenic ou en lithium supérieures à leur critère respectif pour toute la durée des essais. Les concentrations en cuivre, en nickel, en antimoine et en zinc dans les lixiviats des deux cellules restent en dessous de leur critère RES respectif tout au long des 100 semaines d'essai.

Sur la base de ces résultats, le minerai pourrait présenter un potentiel de lixiviabilité en arsenic et, à titre indicatif, en lithium à très court terme. Étant donné que les deux échantillons présentent des comportements différents, la représentativité des propriétés géochimiques de l'échantillon CV-WR-HCT-74 devrait être évaluée par rapport aux propriétés de la lithologie complète. Il est également recommandé de procéder à des essais de lixiviation en colonne sur le minerai afin de mettre à l'essai une masse plus grande d'échantillon dans des conditions plus représentatives des conditions de terrain.

6.2.3.3 Lixiviabilité des résidus miniers

Les essais cinétiques en colonne réalisés sur cinq échantillons de résidus miniers (Vision Geochemistry, 2025) confirment une partie des résultats des essais statiques. Quatre de ces échantillons présentent des lixiviats avec des concentrations qui dépassent les critères RES et D019 de l'arsenic, pendant toute la durée des essais, c'est notamment le cas de l'échantillon composite représentatif des résidus miniers qui seront entreposés sur le site (colonne CL-5). Les teneurs en chrome dans les lixiviats sont très faibles sur toute la période d'essai pour toutes les colonnes.

Malgré une concentration dans son lixiviat initial dépassant le critère RES pour les résidus miniers de flottation, les concentrations en cuivre mesurées dans les lixiviats sont inférieures à la limite de détection pour tous les échantillons à partir du troisième rinçage. Ce résultat indique l'absence d'un potentiel significatif de lixiviation du cuivre dans les résidus miniers évalués.

Pour l'antimoine, les résultats montrent une diminution graduelle des concentrations au fur et à mesure du déroulement des essais. Après quatre semaines de rinçage, les concentrations deviennent inférieures au critère RES, ce qui illustre une atténuation progressive du potentiel de relargage de cet élément au fil du temps. Des conclusions similaires peuvent être faites pour le lithium.

Les concentrations en uranium de l'échantillon CL-5 restent au-dessus du critère RES pendant huit (8) semaines sur vingt (20). Toutefois, la diminution constante de ces concentrations semble montrer qu'il n'y a pas de problématique de lixiviation à long terme en uranium pour les résidus miniers.

6.2.4 Sommaire sur la lixiviabilité des matériaux miniers

Les essais en cellule humide et les essais en colonne diffèrent principalement par leurs conditions expérimentales : les cellules humides appliquent des cycles standardisés d'humidification-séchage, tandis que les colonnes reproduisent de façon plus représentative les conditions observées sur le terrain. De plus, comme mentionné dans la Section 5.0, les différences de granulométrie des échantillons qui sont soumis à ces essais jouent un rôle prépondérant dans la réactivité des phases minérales présentes. Ces différences peuvent entraîner des comportements de lixiviation distincts selon les lithologies. Le rapport entre la quantité de lixiviat et la quantité de solide lixivié influe également sur les taux de lixiviation. Ce rapport est de l'ordre de 1 pour les essais en cellule humide et de 0,1 pour les essais en colonne. À titre comparatif, ce rapport est de 0,001 à 0,01 pour une halde à stériles (Dent et al., 2022).

Le **Tableau 6-3** synthétise les informations recueillies des différents essais afin de classifier les matériaux quant à leur lixiviabilité en métaux et métalloïdes. La classification est faite sur la base de l'information disponible en considérant que les propriétés des échantillons analysés pour une lithologie sont représentatives des propriétés de l'ensemble de cette lithologie.

Tableau 6-3 Interprétation de la lixiviabilité des lithologies et des résidus miniers

Lithologies/Matériaux	Selon les essais statiques	Selon les essais cinétiques		Classification
		À court terme	À long terme	
Amphibolite	arsenic, cuivre	As Cd Sb	As Cd Sb	Lixiviable
Métasédiments	arsenic, cuivre	As	-	Lixiviables
Ultramafique	arsenic, cuivre, chrome, nickel	As Cd	As Cd	Lixiviable
Pegmatite (stérile)	arsenic	As Cd Cu	-	Lixiviable
Pegmatite à spodumène (minerai)	arsenic	As (Li)*	-	à confirmer par des essais supplémentaires
Résidus miniers (composite)	arsenic, chrome	As U (Li)*	As	Lixiviable

* Le lithium (Li) ne possédant pas de critère RES, son critère CVAA a été utilisé afin de l'intégrer dans l'analyse à titre indicatif.

6.2.5 Matériaux à risques élevés

Dans le cadre des essais réalisés par Vision Geochemistry (2025), lors des essais de lixiviation TCLP, seuls deux échantillons ultramafiques sur huit ont montré des concentrations dans leur lixiviat supérieures au critère des résidus miniers à risques élevés pour l'arsenic. Les concentrations observées dans leur lixiviat étaient de 5,80 mg/L et 7,58 mg/L (critère de 5 mg/L).

La lithologie ultramafique est classée non acidogène (voir **Section 6.1**), ce qui signifie qu'elle ne devrait pas générer des conditions acides comparables à celles qui sont simulées lors de l'essai TCLP. Il est donc peu probable qu'elle produise naturellement un lixiviat présentant des concentrations en arsenic suffisamment élevées pour entraîner une classification « à risques élevés ». De plus, ces deux échantillons ne sont pas représentatifs de l'ensemble de la lithologie, car ils avaient été sélectionnés en raison de leurs teneurs élevées en arsenic. Ils semblent refléter ainsi des cas extrêmes plutôt que le comportement général de la lithologie ultramafique.

Sur la base de ces considérations, il est considéré qu'aucun des matériaux miniers du projet ne soit classé comme « à risques élevés » selon les critères du GCRMM.

6.3 Radioactivité

Une analyse préliminaire de la radioactivité des matériaux miniers du projet a été réalisée. La radioactivité des matériaux miniers provient principalement des isotopes de l'uranium et du thorium ainsi que des radionucléides faisant partie de leur chaine de décroissance. La **Figure 6-9** présente la distribution des teneurs en uranium et en thorium extractible analysés dans le cadre de l'étude de Vision Geochemistry (2025). Les teneurs en ces deux éléments sont faibles, de l'ordre du ppm pour l'ensemble des matériaux miniers du projet. Il semble a priori que la radioactivité potentielle de ces matériaux est faible. Il faut mentionner toutefois que les teneurs présentées sont des teneurs obtenues par digestion partielle des échantillons. Il est donc possible que ces teneurs sous-estiment la teneur totale des matériaux en ces éléments.

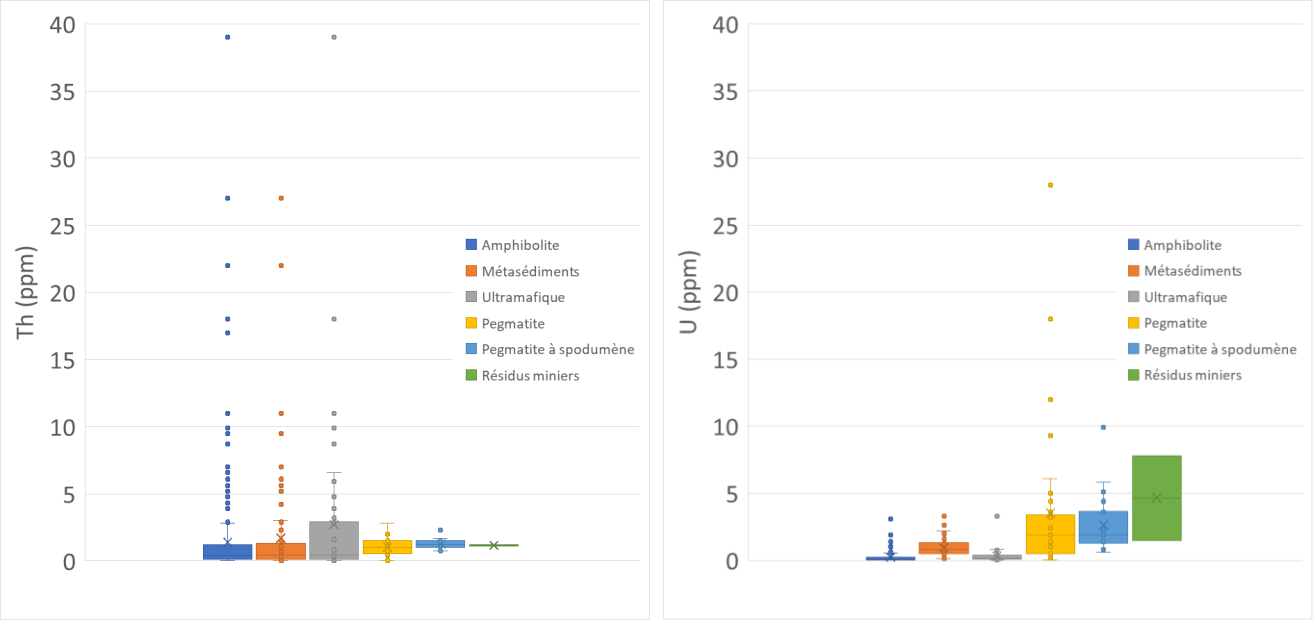

Figure 6-9 Teneurs en thorium et uranium extractibles

Dans le cadre des essais en colonne de l'UQAT, l'activité de certains radionucléides a été mesurée dans les lixiviats des colonnes C1 à C9 au mois 1 des essais et dans ceux des colonnes C3 à C9 au mois 9.

Les isotopes analysés sont le plomb-210, le radium-226 ainsi que le thorium-228, -230 et -232. Les lixiviats du mois 1 des essais en colonne montrent des activités généralement inférieures à la limite de détection, excepté pour les colonnes C4 (métasédiments), C5 (pegmatite stérile) et C7 (métasédiments en conditions submergées). Les isotopes détectés sont le radium -226, le thorium -230 et -232. Les activités les plus élevées sont observées dans le lixiviat de la colonne de pegmatite C5 avec des activités comprises entre 0,11 et 0,19 Bq/L. En comparant l'activité massique de ces radionucléides avec leur activité massique maximale, il est possible d'estimer, de façon partielle, le rayonnement ionisant S associé à chaque lithologie. Les valeurs obtenues pour chaque lithologie sont significativement inférieures au critère définissant les matériaux à risques élevés en termes de radioactivité. La situation est similaire au mois 9 des essais. Les isotopes détectés sont le radium -226 dans les lixiviats de toutes les colonnes, sauf la C6 (amphibolite) et le plomb -210 pour les colonnes C5 (pegmatite) et C6. Les activités sont toutefois trop faibles pour que les valeurs du coefficient S calculées soient supérieures au critère définissant les matériaux miniers à risques élevés. Les activités du radium -226 sont inférieures au critère de l'effluent final de la Directive 019 (0,37 Bq/L) lors de chaque mesure.

L'évaluation préliminaire du potentiel de radioactivité des matériaux miniers du projet semble indiquer qu'il est peu probable que ceux-ci soient classifiés comme radioactifs. Cette affirmation devra être confirmée par la réalisation d'essais permettant le calcul du coefficient de rayonnement S incluant l'ensemble des isotopes requis par le GCRMM.

7. Conclusions et recommandations

Une revue des données géochimiques disponibles a été réalisée afin de mettre à jour la classification des matériaux miniers qui seront produits dans le cadre de l'exploitation du projet Shaakichiuwaanaan selon les critères du Guide de caractérisation des résidus miniers et du minerai du Québec. Les données examinées incluent des résultats d'essais statiques réalisés sur 350 échantillons de stériles, de minerai et de résidus miniers ainsi que des résultats d'essais cinétiques en cellules humides et en colonnes. Une partie de ces résultats a été présentée antérieurement dans le rapport de Vision Geochemistry (2025). Le présent rapport vise à réaliser une validation et une mise à jour de l'interprétation présentée dans le rapport de 2025 sur la base des données additionnelles collectées.

Le **Tableau 7-1** présente une synthèse de la classification des différentes lithologies évaluées dans le cadre de cette revue. Cette vue d'ensemble constitue la base de l'interprétation des risques associés au comportement géochimique des matériaux du projet et servira à bâtir le programme de gestion des matériaux miniers sur le site. La classification est établie sur la base de l'information disponible au moment de cette revue en considérant que les propriétés des échantillons analysés pour une lithologie sont représentatives des propriétés de l'ensemble de cette lithologie.

Tableau 7-1 Classification des lithologies concernées par le projet

Lithologie	Acidogène	Lixiviabilité	À risques élevés	Radioactivité (évaluation préliminaire)
Amphibolite	Non	Lixiviable (**As, Cd, Sb**)	Non	Non
Métasédiments	Non	Lixiviables (As)	Non	Non
Ultramafique	Non	Lixiviable (**As, Cd**)	Non	Non
Pegmatite stérile	Non	Lixiviable (As, Cd, Cu)	Non	Non
Pegmatite spodumène	Non	Potentiellement lixiviable (As, Li), à confirmer par des essais supplémentaires	Non	Non
Résidus miniers	Non	Lixiviables (**As**, Li, U)	Non	Non

Note : les éléments **en gras** sont plus susceptibles d'être lixiviés sur le long terme selon les résultats des essais en colonne

Il est à noter que, dans le cadre du rapport de Vision Geochemistry (2025), plusieurs lithologies avaient été identifiées comme potentiellement acidogènes de façon préliminaire. À la lumière de l'information supplémentaire qui a été examinée dans le cadre de la présente étude, ce potentiel n'a pas été confirmé. L'ensemble des matériaux miniers du projet est considéré comme non acidogène. Il est toutefois recommandé de poursuivre les essais dans des conditions plus représentatives des conditions de l'exploitation afin de valider cette information.

Bien que toutes les lithologies aient été classifiées comme non acidogènes, la lithologie des métasédiments serait la plus sensible à une hétérogénéité de la distribution en sulfures ou en minéraux neutralisants. En effet, cette unité présente les teneurs en soufre les plus élevées et des teneurs en carbonates parmi les plus faibles. Le risque environnemental que pourrait représenter cette unité doit être évalué plus en détail.

Aucun matériau minier du projet n'a été classé comme « à risques élevés » dans le cadre de cette revue. Toutefois, les essais en colonne sur la roche ultramafique montrent des concentrations lixiviées de plus de 5 mg/L pour l'arsenic. Des essais à plus grande échelle doivent être mis en œuvre afin de vérifier les concentrations lixiviées dans les conditions du terrain.

Selon les résultats d'analyses disponibles, l'ensemble des matériaux miniers présentent un certain potentiel de lixiviabilité à court terme (métasédiments, pegmatite) ou à plus long terme (amphibolite, ultramafique et résidus miniers). Vision Geochemisty (2025) propose la mise en place d'un procédé de ségrégation permettant de séparer le stérile en deux groupes, l'un étant constitué de matériel à faibles risques, l'autre comprenant le matériel lixiviable et acidogène. Des essais de laboratoire débuteront en mars 2026 pour tester ces critères de ségrégation sur les différents matériaux miniers du projet et de vérifier la possibilité de produire du matériel à faible risque sur la base de ceux-ci.

Au terme de cet exercice, plusieurs recommandations peuvent être formulées afin d'améliorer la connaissance des propriétés des matériaux miniers du projet et de permettre une gestion adéquate de ceux-ci durant l'exploitation. Ces recommandations tiennent compte des commentaires de l'Agence d'évaluation d'impact du Canada (AEIC) qui ont été reçus par PMET en février 2026. Elles sont les suivantes :

- Étudier la répartition spatiale des éléments potentiellement problématiques (soufre, arsenic, antimoine, etc.) au sein du gisement afin de localiser les zones potentiellement enrichies. Les propriétés géochimiques de ces zones peuvent être différentes par rapport aux propriétés moyennes de la lithologie dans laquelle elle se retrouve.
- Réaliser des essais de lixiviation à plus grande échelle, avec une granulométrie représentative de celle observée dans les haldes à stériles, et dans les conditions d'altération du site.
- Réaliser des essais de validation des critères de ségrégation en laboratoire afin de vérifier la possibilité d'isoler un matériel à faibles risques à partir des lithologies stériles sur la base de ces critères.
- Réaliser un essai en colonne sur un composite d'échantillons représentatifs du minerai afin de finaliser la classification pour cette lithologie ;
- Examiner la représentativité des propriétés géochimiques de l'échantillon de minerai de la cellule humide CV-WR-HCT-74 par rapport aux propriétés de la lithologie complète ;
- Procéder à l'évaluation de la radioactivité des différentes lithologies/matériaux miniers du projet selon les exigences du GCRMM (évaluation du coefficient de rayonnement S) ;
- Analyser la composition minéralogique des résidus miniers, car ces données ne sont pas disponibles actuellement ;
- Augmenter le nombre d'analyses de la composition minéralogique des lithologies stériles sur des échantillons représentatifs afin, entre autres, de mieux identifier les minéraux neutralisants de l'unité de métasédiments ;

- Vérifier si un phénomène d'adsorption du nickel retarde l'émission de cet élément dans les lixiviats de la lithologie ultramafique ;
- Validation en conditions opérationnelles : Bien que les essais statiques et cinétiques offrent un cadre robuste, un programme de suivi en conditions réelles d'exploitation permettra également de confirmer les comportements anticipés.

Il est à noter que les travaux de caractérisation géochimique des matériaux miniers qui seront produits par le projet se poursuivent en 2026. Des essais de lixiviation sont en cours de démarrage au laboratoire et des essais de lixiviation en barils ont débuté en octobre 2025 sur le site de la future exploitation minière. Les recommandations mentionnées ci-dessus seront intégrées à ce programme de caractérisation.

Notice to Reader

This report has been prepared and the work referred to in this report has been undertaken by AtkinsRéalis Canada Inc. (AtkinsRéalis), for the exclusive use of Patriot Battery Metals Inc., who has been party to the development of the scope of work and understands its limitations. The methodology, findings, conclusions and recommendations in this report are based solely upon the scope of work and subject to the time and budgetary considerations described in the proposal and/or contract pursuant to which this report was issued. Any use, reliance on, or decision made by a third party based on this report is the sole responsibility of such third party. AtkinsRéalis accepts no liability or responsibility for any damages that may be suffered or incurred by any third party as a result of the use of, reliance on, or any decision made based on this report.

The findings, conclusions and recommendations in this report (i) have been developed in a manner consistent with the level of skill normally exercised by professionals currently practicing under similar conditions in the area, and (ii) reflect AtkinsRéalis' best judgment based on information available at the time of preparation of this report. No other warranties, either expressed or implied, are made with respect to the professional services provided to Patriot Battery Metals Inc. or the findings, conclusions and recommendations contained in this report. The findings and conclusions contained in this report are valid only as of the date of this report and may be based, in part, upon information provided by others. If any of the information is inaccurate, new information is discovered or project parameters change, modifications to this report may be necessary.

This report must be read as a whole, as sections taken out of context may be misleading. If discrepancies occur between the preliminary (draft) and final version of this report, it is the final version that takes precedence. Nothing in this report is intended to constitute or provide a legal opinion.

The contents of this report are confidential and proprietary. Other than by Patriot Battery Metals Inc., copying or distribution of this report or use of or reliance on the information contained herein, in whole or in part, is not permitted without the express written permission of Patriot Battery Metals Inc. and AtkinsRéalis.

1. Introduction

This technical note presents the geotechnical design requirements for the waste management infrastructure on the Shaakichiuwaanaan Project. The site is in the Eeyou Istchee James Bay region of Québec, Canada, with coordinates of 53°32’00” N, 73°55’00” W. It is approximately 220 km east of Radisson and about 240 km north-northeast of Nemaska. The project will extract spodumene from a pegmatite deposit using a hybrid method that includes open-pit and underground mining.

Waste management infrastructure includes Stockpile 001, Stockpile 002, Overburden Pile 004, Overburden Pile 005, and the Organics Pile. The waste to be contained within each structure is as follows:

- Stockpile 001 – 44 Mt of Low-Risk waste rock.
- Stockpile 002 – 80 Mt of potentially acid-generating (PAG) waste rock and 52.7 Mt of DMS tailings with a minimum 10% buffer capacity.
- Overburden Pile 004 – 8 Mt of overburden stripped during mine development.
- Overburden Pile 005 – 8 Mt of overburden stripped during mine development.
- Organics Pile – approximately 1,400 t of organic soils stripped during mine development.

2. Background

The following sections present a general overview of subsurface conditions expected to be encountered within the stockpiles' footprints. Further details regarding material properties of the soil and bedrock, as well as soil profile drawings, can be found in CASN-A-370-GT-MEM-0002, *Foundation Recommendations for Site Infrastructure* [1].

2.1 Overburden

Based on AtkinsRéalis' interpretations of the results from the geotechnical campaign [2], there are six (6) soil units present across the Shaakichiuwaanaan site. Descriptions of these soil units according to their Unified Soil Classification System (USCS) [3] symbols are outlined below:

- Organics (no USCS symbol) – Peat is found at ground level across the site, generally ranging in depth from 0.1m to 0.5 m bgs (below ground surface).
- 'ML': – A soil unit of Silt/Sandy Silt/Silt with Gravel was encountered at generally shallow depths in some boreholes at Stockpiles 001 and 002, the Isolation Dike area, and the Industrial Area.
- 'SM' – A soil unit of Silty Sand/Silty Sand with Gravel was encountered across the site, underlying the proposed footprints of Stockpiles 001 and 002, the Isolation Dike area, and the Industrial Area. The thickness of this soil unit varies across the site.
- 'GM' – A unit of Silty Gravel with Sand/Gravel with Silt and Sand was encountered in some boreholes advanced in Stockpiles 001 and 002, the Isolation Dike area, and the Industrial Area. The thickness of this unit varies at each borehole location.
- 'GW' – A unit of Gravel was encountered in limited boreholes in the Industrial Area and Isolation Dike area. The thickness of this unit varies at each borehole location.
- Cobbles/Gravel (no USCS symbol) – Found across the site overlying bedrock, the thickness varies.

2.1.1 Stockpile 001

The soil conditions encountered in the Stockpile 001 footprint are variable and are as follows:

- Organics are encountered across the whole footprint, ranging from 0.1 to 0.9 m thick (average 0.4 m) with the greatest depth at the centre of the footprint. Organics directly overlay bedrock at the eastern edge of the footprint.
- ML is encountered only on the western edge of the footprint to depths ranging from 0.8 to 1.4 m bgs, overlaying GM and cobbles/gravel.
- SM is encountered only on the northern and southern portions of the footprint (not in the centre), overlaying cobbles/gravel or bedrock. This soil unit is found to depths ranging from 0.9 to 3.1 m bgs, with the greatest depth occurring at the northeastern corner of the footprint.
- GM is encountered in select areas at the western edge and centre of the footprint (generally 1 m thick). It is overlain by ML at the western edge and organics at the centre and is underlain by cobbles/gravel.
- Cobbles/gravel are generally found across the whole footprint, except at the eastern edge, directly overlaying bedrock.

2.1.2 Stockpile 002

The soil conditions encountered in the Stockpile 002 footprint are variable and are as follows:

- Organics are encountered across the whole footprint, ranging from 0.1 to 1.5 m thick (average 0.4 m). Depth varies across the footprint with a localised low at the southwestern corner in the footprint of Collection Pond 004.
- ML was encountered only at the northeastern corner of the footprint to a depth of 1.8 m bgs, overlaying SM, GM, and cobbles/gravel.
- SM is encountered across the whole footprint overlaying GM, and/or cobbles/gravel, and bedrock. This soil unit is found to depths ranging from 0.5 to 13.4 m bgs, varying with bedrock surface, with the greatest depth at the centre of the footprint.
- GM is encountered in select areas near the centre of the footprint and at its eastern edge. It is overlain by SM and overlies cobbles/gravel and bedrock. Depth and thickness of the soil unit vary across the footprint.
- Cobbles/gravel is encountered in select areas near the centre of the footprint and at its eastern edge. Depth and thickness of the soil unit vary across the footprint.

2.1.3 Overburden Piles 004 and 005

There is limited borehole information with which to assess the soil conditions which may be expected within the footprints of Overburden Piles 004 and 005. One borehole was advanced at the northwest corner of Overburden Pile 004 (no soil samples were collected) and one borehole with soil sampling was advanced at the northeast corner of Overburden Pile 004, offset about 130 m from the toe of the stockpile. No boreholes were advanced in the vicinity of Overburden Pile 005.

Per surface geology mapping [4], both stockpiles are located within the Ablation Till surface deposit zone which is the same zone as the footprint of Stockpile 001. Using this mapping, it can be deduced that the soil conditions underlying the footprints of the stockpiles are expected to be similar to the conditions encountered at Stockpile 001. At the northwest corner of Overburden Pile 004, overburden was encountered to a depth of 14 m. Northeast of the Overburden Pile 004 footprint, organic material directly overlies bedrock to a depth of 0.3 m.

The above assessment is based on limited information; it is recommended that additional geotechnical boreholes and testing be conducted within the vicinity of Overburden Piles 004 and 005 in subsequent phases of design.

2.1.4 Organics Pile

There is limited borehole information with which to assess the soil conditions which may be expected within the footprint of the Organics Pile. Geotechnical boreholes have been advanced in its general vicinity, however, they are offset from the toe of the stockpile by a minimum of 200 m.

To the north of the pile, organics directly overly bedrock to a depth of 0.6 m. South and southwest of the stockpile, organics and ML overly SM soil to a maximum depth of 1.2 m; SM soil extends to bedrock at about 6 m. East of the pile, SM soil extends to about 3 m, overlying cobbles/gravel which itself extends to about 4 m.

Based on the above and considering the Organics Pile is located within the Ablation Till surface deposit zone, soil conditions underlying the Organics Pile are expected to be similar to those encountered at Stockpile 001.

The above assessment is based on limited information; it is recommended that additional geotechnical boreholes and testing be conducted within the Organics Pile footprint in subsequent phases of design.

2.2 Bedrock

As per the Preliminary Economic Assessment [5], the site covers a significant portion of the Lac Guyer Greenstone Belt, which is part of the larger La Grande River Greenstone Belt. It is primarily composed of volcanic rocks that have been metamorphosed to amphibolite facies. During the geotechnical campaign [2], the encountered bedrock within the footprints of Stockpiles 001 and 002 were predominantly Guyer Group amphibolite and metasediments. Per the borehole logs from the geotechnical campaign, the rock quality designation (RQD) of the bedrock encountered in the Industrial Area and Stockpile footprints is Good to Excellent and the strength ranges from Strong to Extremely Strong (per International Society for Rock Mechanics (ISRM) classification).

Depth to bedrock within the Stockpile 001 footprint ranges across the footprint from 0.6 to 5.7 m bgs; elevation of the bedrock surface ranges from 360 to 392 m asl (above sea level). It generally dips northwest; its greatest depth is at the western edge and its shallowest is at the eastern edge.

Depth to bedrock within the Stockpile 002 footprint ranges across the footprint from 0.3 to 18.8 m bgs; elevation of the bedrock surface ranges from 374 to 440 m asl. Bedrock is at its highest elevation at the centre of the eastern half of the footprint and is at its lowest elevation at the centre of the western half of the footprint.

The limited borehole information in the vicinity of Overburden Piles 004 and 005 indicates the bedrock elevation within the footprint of the stockpiles is likely variable and may range from 387 to 350 m asl.

The limited borehole information in the vicinity of the Organics Pile indicates the bedrock elevation within the footprint is likely variable and may range from about 389 to 370 m asl.

2.3 Groundwater

Within the footprint of Stockpile 001, groundwater depths range from 0.13 to 0.51 m bgs. With the variations in ground surface, groundwater elevations range from 365 to 389 m asl.

Within the footprint of Stockpile 002, groundwater depths range from 2.08 to 3.07 m bgs. With the variations in ground surface, groundwater elevations range from 393 to 418 m asl.
At the time of writing, groundwater information was not available for Overburden Piles 004, 005, or the Organics Pile.

Groundwater depth readings were taken between July and October 2024; seasonal changes to levels may be expected.

3. Stockpile 001

3.1 Mine Waste and Stability Hazard Classification

Stockpile 001 will hold about 44 Mt of Low-Risk waste rock. Based on the Low-Risk rating, a base lining system will not be required for Stockpile 001.

Stability hazard classification has been evaluated based on the Hawley and Cunning, 2017 Waste Dump and Stockpile Stability Rating and Hazard Classification (WSRHC) system [6]. This system considers factors such as regional setting, foundation conditions, material quantities, stockpile geometry, and stability to determine a Waste Dump and Stockpile Hazard Class (WHC). WHC is rated on a scale of I to V (1 to 5), with WHC I being very low instability hazard and WHC V being of very high instability hazard. Per the WSRHC system, Stockpile 001 has been assigned a rating of WHC III (Moderate Hazard).

3.2 Foundation Recommendations

It is recommended that all organics and loose materials be removed from the stockpile footprint. The ML may require removal if it is found to be loose and/or saturated, following inspection by a geotechnical engineer. The SM, GM, and cobbles/gravel soil units are considered adequate material for the stockpile foundation, however, they should be inspected by a geotechnical engineer to confirm suitability prior to the placement of waste rock. In some portions of the footprint, after removal of organics, it is possible for waste rock to be placed directly on bedrock.

Due to the geochemical nature of the waste rock to be placed in Stockpile 001, no geomembrane liner is required to be installed.

The recommendations above have been based on field testing of the in-situ soils. More advanced soil testing (e.g. direct shear, triaxial) should be undertaken in subsequent phases of design to determine shear strength and other geotechnical properties of the foundation soils.

3.3 Stockpile Design

3.3.1 Operations

Waste rock will be placed in 10 m high lifts. It is assumed that intermediate slopes of 1.5H:1V will be used. Note that, if preferred, 5 m high lifts can also be accommodated. For each 10 m lift, a 15 m bench will be constructed. For every third lift, the bench will be 22.5 m wide. The maximum height of Stockpile 001 is about 90 m (measured from the downstream toe to the maximum elevation).

Figure 3-1 below depicts a typical cross-section of Stockpile 001. Safety berms are provided at the edge of each bench. The height of the safety berms should be the axle height of the dump trucks. Steeper intermediate slopes can be used if required and if so, the width of the berm should be increased to ensure the overall slope is maintained as shown.

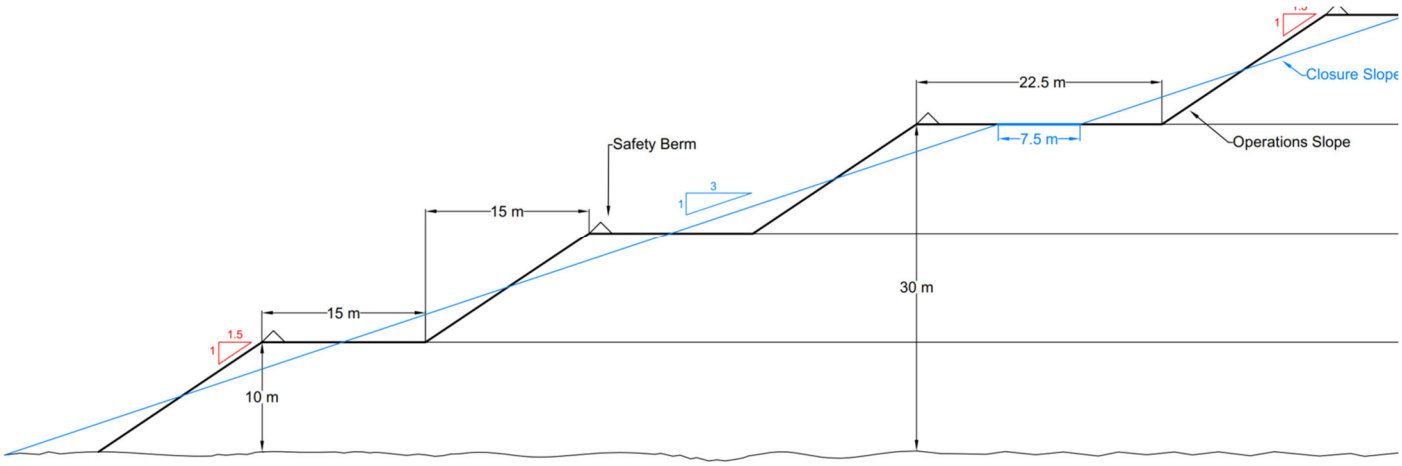

Figure 3-1: Typical Cross-Section of Stockpile 001, Operations and Closure

3.3.2 Closure

During the closure phase, the intermediate slopes will be flattened to a 3H:1V slope to form a uniform slope for every three (3) benches/lifts. Every third bench will be maintained at a width of 7.5 m for water management purposes. The closure slope is depicted in
Figure 3-1.

4. Stockpile 002

4.1 Mine Waste and Stability Hazard Classification

Stockpile 002 will hold about 80 Mt of PAG waste rock and 52.7 Mt of DMS tailings with a minimum of 10% buffer capacity. The PAG waste rock will be stored separately from the tailings within the stockpile footprint. The entire footprint of the stockpile will require a single layer of high-density polyethylene (HDPE) geomembrane liner. Further details of the base lining system are outlined in **Section 4.2.**

Per the WSRHC system, as described in **Section 3.1**, the waste rock and tailings portions of Stockpile 002 have been assigned a rating of WHC III (Moderate Hazard).

4.2 Foundation Recommendations

It is recommended that all organics and loose materials be removed from the stockpile footprint. The ML may require removal if it is found to be loose and/or saturated, following inspection by a geotechnical engineer. The SM, GM, and cobbles/gravel soil units are considered adequate material for the stockpile foundation, however, they should be inspected by a geotechnical engineer to confirm suitability prior to the placement of waste rock.

Due to the geochemical nature of the tailings to be placed in Stockpile 002, a geomembrane liner is required to be installed. The 1.5 mm thick HDPE geomembrane liner may be placed on the compacted foundation soils. A 1 m thick cushion layer will be required between the liner and waste material. The requirements for an overdrainage system, above the liner, are under review.

The recommendations above have been based on field testing of the in-situ soils. More advanced soil testing (e.g. direct shear, triaxial) should be undertaken in subsequent phases of design to determine shear strength and geotechnical properties of the foundation soils.

4.3 Stockpile Design

4.3.1 Operations for Filtered Tailings

The tailings portion of the waste will be placed in thin layers of about 300 mm, spread with a dozer and compacted with a vibratory roller. The external slope of the filtered tailings will be 3H:1V. Once the height of the placed filtered tailings has reached 30 m, a bench of 7.5 m will be provided. The benches will be provided for every 30 m of placed tailings. The maximum height of Stockpile 002 is about 125 m (measured from the downstream toe to the maximum elevation). **Figure** 4-1 below depicts a typical cross-section of the filtered tailings in Stockpile 002.

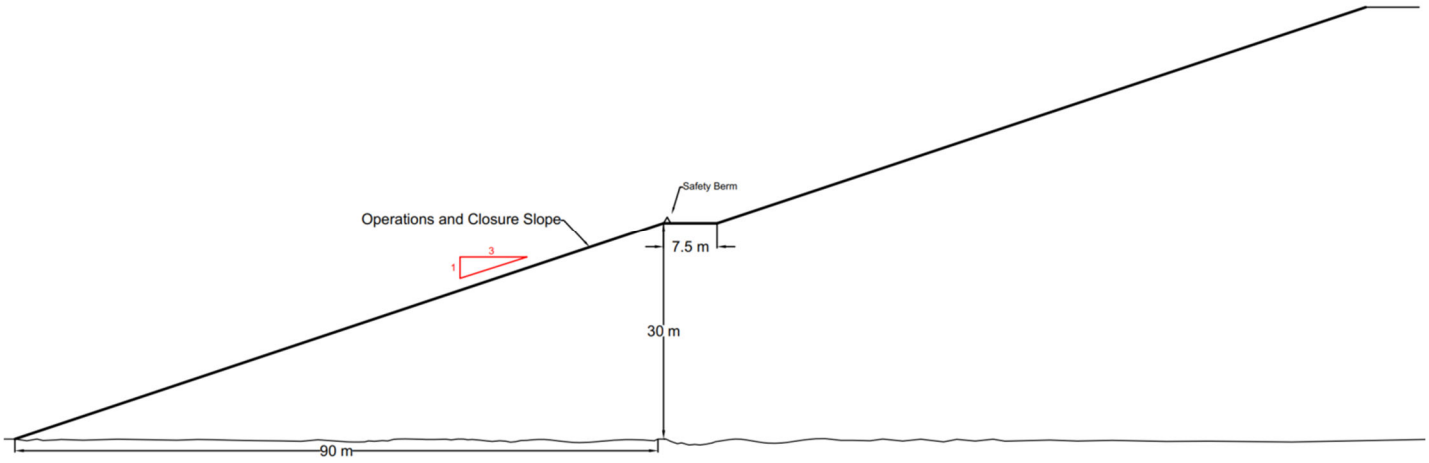

Figure 4-1: Typical Cross-Section of Tailings in Stockpile 002, Operations and Closure

4.3.2 Operations for Waste Rock

Operations of the waste rock portion of Stockpile 002 will have the same methodology as for Stockpile 001, as described in **Section 3.3.1** and depicted in
Figure 3-1.

4.3.3 Closure

The intention of constructing the profile for the filtered tailings during the operation period is that this profile will be maintained at closure to match the adjacent waste rock.

5. Overburden Piles 004 and 005

5.1 Mine Waste and Stability Hazard Classification

Overburden Piles 004 and 005 will each hold about 7.5 Mt of overburden soils. These soils are considered to be non-acid generating (NAG) thus, a base lining system will not be required for Overburden Piles 004 and 005.

Due to the low maximum height of the piles, very flat slope, and NAG properties of the soils, the piles have not been assigned a WHC rating per the WSRHC system, as described in **Section 3.1**.

5.2 Foundation Recommendations

It is recommended that all organics and loose materials be removed from the pile footprints. The ML, if encountered, may require removal if it is found to be loose and/or saturated, following inspection by a geotechnical engineer. The SM, GM, and cobbles/gravel soil units are considered adequate material for the stockpile foundations, however, they should be inspected by a geotechnical engineer to confirm suitability prior to the placement of soils. In some portions of the footprint, after removal of organics, it may be possible for soils to be placed directly on bedrock.

Due to the geochemical nature of the overburden soils to be placed in the piles, no geomembrane liner is required to be installed.

The recommendations above have been based on field testing of the in-situ soils. More advanced soil testing (e.g. direct shear, triaxial) should be undertaken in subsequent phases of design to determine shear strength and other geotechnical properties of the foundation soils.

5.3 Overburden Pile Design

5.3.1 Operations

Overburden Pile 004 will reach its maximum capacity during Year 4 of operations. Overburden Pile 005 will reach its capacity during Year 9. Operations for both Overburden Piles 004 and 005 will be similar. The overburden soils can be placed in layers of about 750 mm, spread with a dozer and compacted with a vibratory roller. The external slope of the stockpiles will be 4H:1V; no benching will be required. The maximum height of Overburden Pile 004 is about 34 m and the maximum height of Overburden Pile 005 is about 39 m (both measured from the downstream toe to the maximum elevation). A typical cross-section of the overburden piles is shown in **Figure** 5-1.

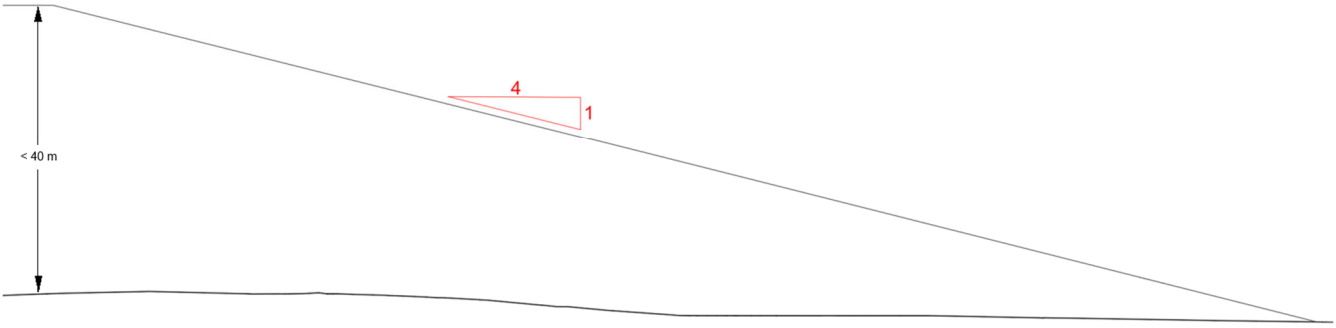

Figure 5-1: Typical Cross-Section of Overburden Piles 004 and 005, Operations and Closure

5.3.2 Closure

The overburden piles are considered temporary structures. Soil will be sourced from these piles for use in closure activities which may commence during life-of-mine operations. If there is remaining overburden, the slopes should be profiled to 4:1 or flatter.

6. Organics Pile

6.1 Mine Waste and Stability Hazard Classification

The footprints of Stockpile 001 and 002 will be stripped of topsoil and organics and placed in the Organics Pile. The Organics Pile is considered a temporary structure and the material will be used for the closure of at least Stockpile 001 and possibly also for Stockpile 002. This pile will hold about 0.8 Mm^3 of organic soils (i.e. peat) and topsoil, equivalent to approximately 1,400 t. This soil is considered to be NAG and thus, a base lining system will not be required.

Due to the low maximum height of the pile and NAG properties, the pile has not been assigned a WHC rating per the WSRHC system, as described in **Section 3.1**.

6.2 Foundation Recommendations

The foundation of the Organics Pile should be inspected by a geotechnical engineer to confirm suitability prior to the placement of soils. It is expected that the existing topsoil within the footprint can stay in place but loose and/or saturated material shall be removed.

Due to the geochemical nature of the organics to be placed in the pile, no geomembrane liner is required to be installed.

The recommendations above have been based on field testing of the in-situ soils. More advanced soil testing (e.g. direct shear, triaxial) should be undertaken in subsequent phases of design to determine shear strength and other geotechnical properties of the foundation soils.

6.3 Pile Design

6.3.1 Operations

The organic soil will be dumped and spread and an external slope of 5H:1V will be formed; no benching will be required. Compaction of the organic soil is not required, but some compaction of the outer slope may be required to reduce sedimentation in the run-off. The maximum height of the Organics Pile is about 27 m (measured from the downstream toe to the maximum elevation). A typical cross-section of the stockpile is shown in **Figure** 6-1.

Figure 6-1: Typical Cross-Section of the Organics Pile

6.3.2 Closure

The intention of constructing the profile for the Organics Stockpile during the operation period is that this profile will be maintained until organics material is required for closure activities. It is anticipated that during the closure phase, all the material in this pile will be utilized. Some closure activities may commence during life-of-mine operations.
