Executive Summary

Project Description

This report describes the geochemistry of KSM Project materials: mine waste rock and pit wall material, tailing material from pilot plant metallurgical testing, non-deposit material, and groundwater seeps related to the KSM Project (the Project). The Project is centred on a gold/copper deposit located in mountainous north-western British Columbia (BC); approximately 950 km northwest of Vancouver and 20 km southwest of Barrick Gold's recently closed Eskay Creek Mine. The proponent for the Project is Seabridge Gold Inc. (Seabridge).

The overall objective of the Project geochemistry baseline is to provide sufficient data for waste rock and water management plans, and an environmental effects assessment. The KSM geochemistry program started in 2008 and has followed a phased approach to metal leaching (ML) and acid rock drainage (ARD) prediction and management. This report includes a cumulative update on baseline data (2008-2012).

The Project has components in two geographically separated areas: the Mine Site and the Processing and Tailing Management Area (PTMA). The proposed Mine Site is located in the drainage basin of Sulphurets Creek, a major tributary of the Unuk River. Waste rock from the development of four deposits (Kerr, Sulphurets, Mitchell, and Iron Cap) will be stored in engineered facilities, and contact water will be collected at a Water Storage Facility (WSF) and treated at a Water Treatment Plant (WTP). Ore material will be crushed in the Mitchell Creek Valley and transported through a 23-km long Mitchell-Treaty Tunnel (MTT) to a Process Plant located in the upper reaches of Teigen and Treaty Creeks. The Process Plant will process approximately 130,000 tonnes of ore per day, generating approximately 1,200 tonnes of concentrate per day. Tailing material will be stored in a multi-stage TMF, which will have a separate lined sulphide containment unit.

Provincial policy suggests that ML /ARD prediction should be undertaken whenever significant amounts of bedrock or unconsolidated material is excavated or disturbed so that, if necessary, prevention, mitigation, and monitoring plans can be implemented. Long-term environmental management at the Project will include ML/ARD prediction, ML/ARD prevention, mitigation strategies, and adherence to receiving environment guidelines (e.g., Metal Mining Effluent Regulations (SOR/2002-222).

Geology

The Sulphurets District is located along the eastern side of the Coast Mountains (Cretaceous to Early Tertiary intrusions and high grade metamorphics) and the western edge of the middle Jurassic to Cretaceous Bowser basin. The District is centred over the breached core of the northerly plunging McTagg anticlinorium, which exposes rocks of the Stuhini Group, unconformably overlain by the Hazelton Group rocks. The upper Triassic Stuhini Group has two main subdivisions: (1) lower dominantly sedimentary units and (2) upper dominantly volcanic and volcanoclastic units. The lower Jurassic Hazelton Group is inferred to represent a volcanosedimentary island arc and back arc complex containing basal sediments overlain successively by volcanic/volcanoclastic units, felsic pyroclastic units, and marine sedimentary units.

The northern portions of the Project are dominated by rocks of the Middle Jurassic to Middle Cretaceous Bowser Lake Group, a marine and continental sedimentary succession inferred to have accumulated in a back arc environment. The Hazelton sequence is intruded by Early Jurassic porphyritic intrusions collectively referred to as the Mitchell Intrusion or Texas Creek Plutonic Suite.

Regional tectonic events attributed to the accretion of terranes have resulted in thrust faulting and widespread folding in the district.

Mike Lechner, of Resource Modelling Inc., constructed acid-base accounting (ABA) block models for the KSM Project in 2010 and 2011. The resolution of individual model blocks is 25 m x 25 m x 15 m; this represents a volume suitable for large excavators to segregate materials on a pit-bench. The block model codes used in the 2011 program are summarized in Table 1.

Table 1. Block Model Codes and Associated Descriptions

Block Model Codes	Description
Kerr	
KERR	All of the Kerr Deposit
Sulphurets	
Overburden	> 50% soil or glaciofluvial material
UP Hazelton	Default for Sulphurets material above STF
Monzonite	Monzonite intrusion
LP Hazelton	Default for Sulphurets below STF
Lower Au zone	Sulphurets low grade ore zone
Au, leach, Raewyn zones	Default for Sulphurets ore zones
Undefined	Default for edge effects or minor units
Mitchell	
Overburden	> 50% soil or glaciofluvial material
Monzonite	Monzonite intrusion
UP Hazelton	Default material above MTF on north or south side of Mitchell Creek
Leach breccia/bornite breccia	Mitchell ore zone
LP Hazelton	Default material below MTF on north or south side of Mitchell Creek
Undefined	Default for edge effects or minor units
Iron Cap	
IRON CAP	All of the Iron Cap deposit

LP = lower panel
UP = upper panel
MTF – Mitchell Thrust Fault
STF = Sulphurets Thrust Fault

Summary of Sampling Plan

Waste rock and potential pit wall material were assessed in 2,030 acid-base accounting (ABA) tests, 40 humidity cells, four sub-aerial drip columns, 17 field leach barrels, three meteoric water mobility protocol leachates (MWMP), and 84 net acid generating (NAG) tests. Tailing material was assessed in eight humidity cells, six subaqueous columns (SAC), and three aging tests. Non-deposit material was assessed in 223 ABA tests, and four shake flask extraction (SFE) leachate tests. Water from 38 groundwater seeps was sampled during the 2009, 2010 and 2012 field programs.

Waste Rock and Pit Wall Characterization – Static Testing

ABA test results of the 2,030 waste rock and pit wall material samples are summarized, by deposit, in Table 2 below.

Table 2. Summary of ABA Test Results for Waste Rock and Potential Pit Wall Material

Deposit	% Samples with Paste pH > 6.0	Range Total-Sulphur (%)	Total-Sulphur and Sulphide-Sulphur Relationship	Range of Sobek NP (kg $CaCO_3$/t)	Sobek NP Correlation	% Samples with Adjusted SNPR < 2.0	% of Deposits Waste Rock with Adjusted SNPR < 2.0
Kerr	81.3	0.01-13.81	Strong	0-259	Strong Ca CaNP	81.3	99.2
Sulphurets	100.0	0.01-7.50	Strong	5-350	Strong Ca CaNP	43.0	33.0
Mitchell UP	100.0	0.03-12.75	Strong	125-342	Moderate Inorg NP	75.3	79.0
Mitchell LP	91.5	0.07-19.05	Moderate	0-263	Strong Inorg NP	92.4	
Iron Cap	92.1	0.11-11.86	Strong	0-258	Strong Ca CaNP	92.0	100.0

NP = neutralization potential
SNPR = sulphide net potential ratio
Ca CaNP = calcium calculated neutralization potential
Inorg NP = inorganic neutralization potential
UP = upper panel
LP = lower panel

Waste Rock and Pit Wall Characterization – Humidity Cell Testing

The 40 humidity cells of waste rock and pit walls represent 99% of Kerr waste rock, 36% of Sulphurets waste rock, 94% of Mitchell waste rock, and 100% of Iron Cap waste rock (Table 3).

Table 3. KSM Waste Rock Model Codes Represented by Humidity Cells

Humidity Cell Identification	Waste/Ore	Weeks Operated	Status

UP = upper panel
LP = lower panel

ABA testing of humidity cell material completed prior to initializing the kinetic tests was compared to the range of all static test results for the model code that the humidity cell represents. The paste pH values for humidity cells was within the interquartile range of all static results, but slightly biased toward the lower end of the range. The adjusted sulphide net potential ratio (SNPR) values for humidity cells spanned the interquartile range of all static results for most model codes; Sulphurets overburden, Mitchell UP Hazelton, and Mitchell LP Hazelton had some adjusted SNPR values that were well below the interquartile range.

In general, sulphate production was high for the 40 waste rock humidity cells, there was no detectable alkalinity, and acidity followed pH trends in the acidic humidity cells. Aluminum and iron concentrations were controlled by pH, with acidic humidity cells producing leachate with higher concentrations. Elements associated with neutralization (calcium and magnesium) had slowly decreasing leach rates or were stable, indicating consumption of available neutralization potential (NP), while acidic cells where pH decreased below 3, had increased calcium and magnesium leach rates concomitant with increased sulphate production.

Four humidity cells were initiated to assess the KERR model code (Table 2). All four cells are predicted to become acidic based on adjusted SNPR values. Cells HC20 and HC22 are near-neutral after 89 weeks, and HC21 and HC23 were acidic early in the test.

Seven humidity cells were initiated to assess Sulphurets material (Table 3). Based on adjusted SNPR values, humidity cell S-06-04 (UP Hazelton) is the only cell predicted to remain at a near-neutral pH. To date, the only cell to produce an acidic leachate is S-06-05 (Overburden); this cell represents potential ore-grade material.

Twenty three humidity cells — eight upper panel and 15 lower panel — were initiated to assess Mitchell material (Table 3). Based on adjusted SNPR values, only two cells are not expected to become acid-generating (NM-05-03 and M-07-30). Currently five humidity cells (HC2, M-06-14, M-07-43, HC1, and HC15) are producing leachate with a pH less than 6.0.

Six humidity cells were initiated to assess Iron Cap material (Table 3). Based on adjusted SNPR values, all cells will become acid-generating; three cells (HCT-3, -4, and -6) are already producing leachate with a pH less than 6.0.

Based on production rates of sulphate, calcium, and magnesium, a predicted time to the depletion of bulk NP or carbonate NP can be calculated. For the samples assessed from the Project area, there was disagreement between results from the two calculation methods. Notably, two monzonite humidity cells with adjusted SNPR values greater than 2.0 are predicted to become acid-generating based on the carbonate NP depletion calculation, but will never become acidic based on the bulk NP calculation.

Waste Rock and Pit Wall Characterization – Field Leach Barrel Testing

Between 2009 and 2010 seventeen field leach barrels were constructed to represent waste rock and pit wall material from the Kerr, Sulphurets, and Mitchell Deposits. ABA pre-test results of field leach barrel material indicated that most of the material chosen is within the interquartile range for material of the same model code. In October 2010, the original 12 field leach barrels were reconstructed to increase the surface area to volume ratio of the material, and to allow for greater air circulation within the barrel.

Kerr and Sulphurets material is represented by four barrels (Table 4). The pH of Kerr and Sulphurets field leach barrel leachate dropped below 6.5 at least once for each barrel. The barrels had variable pH values for the first 20 months, but stabilized during the 2011 field season.

Mitchell upper panel material is represented by seven field leach barrels; Mitchell lower panel is represented by six field leach barrels (Table 4). The leachate pH for Mitchell material was variable and dropped below 6.5 at least once per barrel. Barrels 13 and 17 immediately produced leachate with a pH less than 3.0. Sulphate loadings followed the same general trend, increasing from June to September and then decreasing September to November. This cyclic trend is weakly expressed in some of the trace elements, most notably in Barrel 17.

Waste Rock and Pit Wall Characterization – Sub-Aerial Drip Column Testing

Four sub-aerial drip columns were initiated to assess waste rock and pit wall material from the Mitchell Pit. The sub-aerial drip columns contained the same material as four field leach barrels (Mitchell UP Hazelton, Mitchell Monzonite, and Mitchell LP Hazelton). ABA pre-test results of the sub-aerial drip column material demonstrate that the material chosen is within the interquartile range for material of the same model code.

The leachate pH for all four sub-aerial drip columns across 107 weeks was near-neutral, at approximately 8, and the sulphate concentrations were less than 100 mg/L.

Table 4. Field Leach Barrel Construction Materials

Barrel ID	Zone	Model Code	Barrel ID	Zone	Model Code
Barrel 9	Kerr	KERR	Barrel 4	Mitchell LP	LP Hazelton UP Hazelton

Waste Rock and Pit Wall Characterization – Leachate Testing

NAG tests were performed on six Kerr, seven Sulphurets, and 36 Mitchell samples. The ABA pre-test results displayed a range of paste pH values (3.2 to 9.9). The net neutralization potential (NNP) of all 49 samples indicated that the samples should be classified as potentially acid-generating (PAG). All 49 samples went through an initial two-cycle NAG test, and then through the modified single addition test. All samples were classified as potentially acid-forming (PAF).

NAG test liquor was analyzed by inductively coupled plasma – mass spectroscopy (ICP-MS) and compared to the pre-test concentrations. Based on the assumption that the hydrogen peroxide preferentially oxidizes sulphide phases, sulphide phases were the primary reservoir for cadmium and copper, but not for aluminum and iron.

Tailing Material Characterization – Static Testing

Static tests were performed on 35 tailing samples: Mitchell Rougher tailing (1), Mitchell Rougher-coarse tailing (1), Mitchell Rougher-fine tailing (1), Mitchell Sulphide (pyrite) tailing (1), Mitchell Rougher/Sulphide tailing (1) (combined at a ratio equivalent (90:10) to the relative contributions of Rougher and cleaner tailing predicted to report to the TMF) Mitchell/Sulphurets Rougher (4), Mitchell/Kerr Rougher (16) blended tailing, and Iron Cap Rougher tailing (8).

Paste pH values of non-sulphide tailing material from Kerr, Sulphurets, and Mitchell were between 7.8 and 11.1. Iron Cap Rougher tailing samples had paste pH values between 8.4 and 8.8. The Mitchell Sulphide and Rougher/Sulphide tailing had a paste pH of 5.8 and 6.6 respectively.

The median total-sulphur value was 0.35% for Mitchell/Kerr Rougher tailing, 0.12% for Mitchell/Sulphurets Rougher tailing, 0.38% for Mitchell Rougher tailing, 0.07% for Iron Cap Rougher tailing, 3.1% for Mitchell Rougher/Sulphide tailing, and 22.4% for Mitchell Sulphide tailing. The contribution of sulphide-sulphur to total-sulphur varied between 10 and 90%.

NP values were low to moderate for all tailing material; the total range was 1 to 46 kg $CaCO_3$/t. The Mitchell Sulphide tailing had a paste pH of less than 6.0 and a Sobek NP of 6 kg $CaCO_3$/t; all tailing material was assumed to have an unavailable NP of 6 kg $CaCO_3$/t. This assumption resulted in a few samples to have an adjusted NP of zero, indicating no available NP to offset any acid generation. With the exception of Iron Cap Rougher tailing, the bulk of Sobek NP results correlated well with Inorg NP. The Iron Cap Rougher tailing had a better correlation with calcium calculated NP (Ca CaNP), indicating that the NP was related to a mixture of carbonate and Ca-bearing non-carbonate minerals.

Adjusted SNPR values for tailing ranged between a default minimum of 0.01 and a maximum of 24.8. Mitchell Sulphide and Mitchell Rougher/Sulphide samples were classified as PAG as their adjusted SNPR values are less than 2.0.

Mitchell Sulphide and Mitchell Rougher/Sulphide tailing material typically had silver, arsenic, cadmium, copper, iron, molybdenum, sulphur, antimony, and selenium concentrations that were greater than three times the global average. The non-sulphide tailing material typically had silver, copper, molybdenum, antimony, and selenium concentrations that were greater than three times the global average.

In general, the mineralogy of the non-sulphide tailing was dominated by quartz, plagioclase, and K-feldspar. The sulphide-bearing tailing had large amounts of pyrite, with some chalcopyrite and molybdenite. Minor amounts of calcite, dolomite, ankerite, and magnesite were noted, typically amounting to less than 1%.

Table 5 summarizes the wet sieve and laser diffraction particle size analysis of the tailing material, displaying the maximum particle size that was found in 50 and 80% of the sample by weight.

Table 5. Maximum Particle Size of Material Comprising up to 50 and 80% of Sample by Weight in Tailing Material

	Max Particle Size (microns)	
Tailing	**50%**	**80%**
Mitchell Rougher-fine	5	12
Mitchell Rougher	44	75
Mitchell Rougher-coarse	100	150
Mitchell/Kerr Rougher	12	16
Mitchell/Sulphurets Rougher	20	89

Tailing Material Characterization – Humidity Cell Testing

Eight humidity cells were established to assess tailing material. Based on adjusted SNPR values, the two sulphide-bearing humidity cells (Mitchell Sulphide and Mitchell Rougher/Sulphide) were expected to become acidic. After an initial three-week stabilization period, the pH of the leachate from all

humidity cells was near-neutral, remaining around pH 8. This trend continued for the non-sulphide-bearing humidity cells. The Mitchell Sulphide humidity cell rapidly became acidic after 12 weeks and stabilized at pH 2.5. The Mitchell Rougher/Sulphide humidity cell leachate gradually became acidic between weeks 12 and 89, before rapidly decreasing to a stable pH of 3. The non-sulphide-bearing humidity cells had a gradual two order of magnitude decrease in sulphate production rates between weeks 3 and 73. The acidic, sulphide-bearing humidity cells had high sulphate production rates consistent with sulphide oxidation. Acidity and alkalinity production rates followed pH trends.

The rates of depletion of sulphide, bulk Sobek NP, and carbonate NP were calculated and used to estimate the time to the onset of ARD and the time to the end of ARD for sub-aerial deposit of tailing. The non-sulphide-bearing humidity cells are predicted to never become acidic. The Mitchell Sulphide and Mitchell Rougher/Sulphide tailing humidity cells are predicted to have a very short time to the onset of ARD (less than 5 years), but the ARD will not extend for a relatively long period of time (less than 20 years).

Tailing Material Characterization – Subaqueous Column Testing

Six subaqueous columns of tailing material were initiated: Mitchell Sulphide, Mitchell Sulphide/Rougher, Mitchell Rougher, Mitchell/Kerr Rougher, Mitchell/Sulphurets Rougher, and Iron Cap Rougher. Porewater pH was higher than supernatant for all subaqueous columns. Mitchell/Sulphurets Rougher porewater produced the only alkaline pH values. Supernatant from Mitchell Sulphide and Mitchell Rougher/Sulphide subaqueous columns became acidic after 40 and 64 weeks, reaching a pH of 3.8, and a pH of 5.17 after 110 weeks in the Mitchell Sulphide and Mitchell Rougher/Sulphide columns respectively. Sulphate concentrations were typically orders of magnitude higher in porewater compared with supernatant.

Tailing Material Characterization – Aging Testing

Three aging tests were conducted on tailing material: Mitchell Sulphide, Mitchell Rougher/Sulphide, and Mitchell Rougher. These materials were allowed to equilibrate with their supernatants for up to 120 days and then periodically sampled. The pH was near-neutral to weakly alkaline for all samples. The sulphate concentration increased gradually, indicating sulphide oxidation.

Metal leaching typically reflected drainage pH and there was generally good agreement across tests. Aluminum, arsenic, cadmium, copper, fluoride, selenium, sulphate, and zinc exceeded guidelines most frequently across various tailing types and under both near-neutral and acidic pH drainage conditions.

Non-Deposit Overburden Material Characterization

Sixty-one overburden samples were collected from the proposed Mine Site, PTMA, and access road locations. The paste pH values for the samples were between 5.9 and 9.0, with mean and median values greater than 6.0. The lowest values were from the vicinity of the proposed Mitchell pit. Total-sulphur was dominated by sulphide-sulphur and varied from below detection limit (0.01%) to 6.78%. Median values from the different locations ranged between 0.04 and 1.22%. Bulk Sobek NP results ranged from 6 to 214 kg $CaCO_3$/t. Teigen Creek Valley and Mitchell Pit had slightly lower values than other locations. The Sobek NP correlated reasonably well with Inorg NP and Ca CaNP, but not with calcium-magnesium calculated NP (CaMg CaNP), indicating that most of the NP is from Ca-bearing carbonates. Mean and median unadjusted SNPR values were consistently above 4.0 for non-deposit overburden located outside the Mitchell Pit, indicating that the majority of overburden material is not-PAG.

Four overburden shake flask extractions were run and the resultant leachate had elevated values for nitrite, pH, sulphate, aluminum, arsenic, cadmium, chromium, cobalt, copper, iron, lead, manganese, molybdenum, nickel, selenium, and zinc.

Non-Deposit Rock Material Characterization

161 rock samples were collected from the three major stratigraphic groups at the Project: Stuhini, Hazelton, and Bowser. One sample represents the Zippa Mountain Plutonic Complex. Paste pH values were typically above 7.0, indicating that most of the material is not currently acid-generating. Approximately 25% of the MP and proposed Sulphurets pit samples had a paste pH ≤ 6. Most of the rock material had low total-sulphur contents. Proposed Mitchell Diversion Tunnel (MDT), Mitchell Pit, Sulphurets Pit, and Sulphurets Laydown Area locations had mean and median total-sulphur values above 0.5%. Sulphide-sulphur was the largest contributor to total-sulphur. Bulk Sobek NP values varied between and within sample locations. Coulter Creek Access Road (CCAR), MDT, Mitchell Pit, and Sulphurets Pit had paste pH values < 6.0 indicating some unavailable NP. Based on adjusted SNPR, samples from the proposed Treaty Creek Access Road (TCAR), McTagg Diversion Tunnel (MTDT), and Sulphurets Laydown Area demonstrated a low potential for acid generation.

Three Mitchell Pit highwall composites were subjected to a meteoric water mobility protocol leachate extraction. The resultant leachate had elevated values for sulphate, aluminum, arsenic, boron, chromium, copper, phosphorus, selenium, vanadium, and zinc.

Groundwater Seep Characterization

Naturally occurring groundwater seeps were sampled at the Kerr Deposit (five seeps), Sulphurets Deposit (one seep), Mitchell Deposit (23 seeps), McTagg Creek Valley (three seeps), and Ted Morris Creek Valley (five seeps). The Mitchell Deposit seeps were classified according to the prevailing model code in the area: LP Hazelton (South), or UP Hazelton volcanics (North).

The pH of all Kerr, Sulphurets, and Mitchell seeps were acidic. Sulphate concentrations at the Kerr and Mitchell seeps frequently exceeded the BC MOE guideline, with values as high as 7,400 mg/L. In general, the trace metal concentrations were very high. Seep flow rates varied greatly between seeps, e.g., K-3 at 0.03 L/s and MS-G at 77.01 L/s. The flow rates at seeps were usually within an order of magnitude at repeat sampling events.

Conclusion

The 2,030 potential waste rock and highwall material samples underwent static ABA testing; selected samples underwent leachate and kinetic tests. Almost all potential waste rock and highwall material collected is considered PAG, except for those with Sulphurets UP Hazelton, Sulphurets Monzonite, and Mitchell Monzonite model codes. Material for 17 tailing kinetic tests underwent static ABA testing; Mitchell Sulphide and Mitchell Rougher/Sulphide material should be classified as PAG material with very short lag times to the onset and depletion of ARD. Overburden and non-deposit rock material had a lower potential for ARD outside of the mine area.

Acknowledgments

The data presented in this report is the cumulative work of several individuals and organizations over a few years.

Static and kinetic analytical work was performed at ALS Environmental, ALS Minerals, and Maxxam Analytics. The authors would like to thank the following laboratory personnel: Amber Springer at ALS Environmental for coordinating the analyses of water samples from field programs, Andre Langlais at ALS Minerals for coordinating kinetic and static testing, and Tim O'Hearn at Maxxam Analytics for coordinating kinetic and static testing and providing expertise on testing methods.

Fieldwork was performed by Rescan personnel or subcontractors and the authors would like to thank the following individuals that no longer work for Rescan: Claudio Andrade for collecting samples and setting up most of the data structure, Gerhard Jacobs for collecting the majority of the non-deposit road alignment samples, Larry Amskold for collecting groundwater seep samples, and Rodney Hughes for helping to reconfigure the field leach barrels into their current set-up.

This program was laid out through the work of two primary individuals: Kevin Morin and Keith Mountjoy, who spent considerable amounts of time setting up the field program and laying the groundwork.

This cumulative baseline report is the work of three primary contributors: Vivian Ferrera for the static test work, Kelsey Norlund for the kinetic test work, and Mark Nelson for the non-deposit test work.

4.7 Methods Used to Calculated Depletion Times and ARD Onset 4-30

5. Deposit Waste Rock Results 5-1
5.1 Static Tests 5-1
5.1.1 Kerr Deposit 5-1
5.1.1.1 Paste pH 5-1
5.1.1.2 Sulphur Species 5-1
5.1.1.3 Neutralization Potential 5-6
5.1.1.4 Sulphide Net Potential Ratios 5-6
5.1.1.5 Whole Rock and Solid-phase Elemental Analysis 5-14
5.1.1.6 Mineralogy 5-14
5.1.2 Sulphurets Deposit 5-18
5.1.2.1 Paste pH 5-18
5.1.2.2 Sulphur Species 5-18
5.1.2.3 Neutralization Potential 5-24
5.1.2.4 Sulphide Net Potential Ratios 5-30
5.1.2.5 Whole Rock and Solid-phase Elemental Analysis 5-30
5.1.2.6 Mineralogy 5-30

5.1.3 Mitchell Deposit 5-38
5.1.3.1 Paste pH 5-38
5.1.3.2 Sulphur Species 5-38
5.1.3.3 Neutralization Potential 5-42
5.1.3.4 Sulphide Net Potential Ratios 5-49
5.1.3.5 Whole Rock and Solid-phase Elemental Analysis 5-49
5.1.3.6 Mineralogy 5-58
5.1.4 Iron Cap Deposit 5-58
5.1.4.1 Paste pH 5-58
5.1.4.2 Sulphur Species 5-58
5.1.4.3 Neutralization Potential 5-58
5.1.4.4 Sulphide Net Potential Ratios 5-64
5.1.4.5 Solid-phase Elemental Analysis 5-64
5.1.4.6 Mineralogy 5-72
5.2 Kinetic Tests 5-72
5.2.1 Humidity Cells 5-72
5.2.1.1 Pre-test Static Test Results 5-72
5.2.1.2 Kinetic Test Results 5-80
5.2.1.3 Post-test Static Test Results 5-150
5.2.1.4 Depletion Times and Onset of Acid Rock Drainage 5-150
5.2.2 Sub-Aerial Drip Columns 5-150
5.2.2.1 Pre-Test Static Test Results 5-150
5.2.2.2 Kinetic Test Results 5-153
5.2.3 Field Leach Barrels 5-159
5.2.3.1 Pre-test Static Test Results 5-159
5.2.3.2 Kinetic Test Results 5-174
5.2.4 Comparison of Deposit Rock Kinetic Test Results 5-214
5.3 Leachate Tests 5-214
5.3.1 Pre-Test Static Results 5-214
5.3.2 Leachate Results 5-214
5.3.2.1 Acid Generation 5-214
5.3.2.2 Metal Leaching 5-214
5.4 Summary: Deposit Rock ML/ARD 5-216

6. Tailing Results 6-1
6.1 Static Tests 6-1
6.1.1 Paste pH 6-1
6.1.2 Sulphur Species 6-1
6.1.3 Neutralization Potential 6-5
6.1.4 Sulphide Net Potential Ratios 6-13
6.1.5 Whole Rock and Solid-phase Elemental Analysis 6-13

6.1.6 Mineralogy 6-17
6.1.7 Particle Size Analysis 6-19
6.1.8 Coarse versus Fine Mitchell Rougher Tailing 6-19
6.2 Kinetic Tests 6-19
6.2.1 Humidity Cells 6-19
6.2.1.1 Pre-test Static Test Results 6-19
6.2.1.2 Kinetic Test Results 6-19
6.2.1.3 Depletion Times and Onset of Acid Rock Drainage 6-35
6.2.2 Subaqueous Columns 6-35
6.2.2.1 pH, Sulphate, Acidity, and Alkalinity 6-37
6.2.2.2 Trace Elements 6-37
6.2.2.3 Elements Associated with the Neutralization Potential 6-46
6.2.3 Aging Tests 6-46
6.2.3.1 pH, Sulphate, Acidity, and Alkalinity 6-46
6.2.3.2 Elements that Contribute to Acidity 6-50
6.2.3.3 Cyanide and Nutrients 6-50
6.2.3.4 Trace Elements 6-50
6.2.3.5 Elements Associated with the Neutralization Potential 6-57
6.2.4 Comparison between Subaqueous Columns and Aging Tests: Mitchell Deposit 6-57
6.3 Summary: Tailing 6-61

7. Non-Deposit Rock Results 7-1
7.1 Overburden Static Tests 7-1
7.1.1 Paste pH 7-1
7.1.2 Sulphur Species 7-1
7.1.3 Neutralization Potential 7-5
7.1.4 Sulphide Net Potential Ratios 7-5
7.1.5 Whole Rock and Solid-phase Elemental Analysis 7-5
7.2 Rock Static Tests 7-5
7.2.1 Paste pH 7-10
7.2.2 Sulphur Species 7-10
7.2.3 Neutralization Potential 7-10
7.2.4 Sulphide Net Potential Ratios 7-10
7.2.5 Whole Rock and Solid-phase Elemental Analysis 7-16
7.3 Leachate Tests 7-16
7.3.1 Overburden Shake Flask Extraction 7-16
7.3.2 Rock Meteoric Water Mobility Protocol 7-16

8. Groundwater Seep Results 8-1
8.1 Seep Geochemistry 8-1
8.1.1.1 pH, Sulphate, Acidity, and Alkalinity 8-1

8.1.1.2 Elements that Contribute to Acidity....8-2
8.1.1.3 Barium 8-2
8.1.1.4 Trace Elements....8-13
8.1.1.5 Elements Associated with the Neutralization Potential....8-13
8.2 Seep Flow Rates 8-13
9. Conclusions 9-1

1. Introduction

The overall objective of the Project geochemistry baseline is to provide data for waste rock and water management plans, and an environmental effects assessment. KSM geochemistry program started in 2008 and is following a phased approach to ML/ARD prediction and management.

1.1 PROJECT PROPONENT

Seabridge Gold Inc. (Seabridge) is the proponent for the proposed KSM Project (the Project), a gold, copper, silver, molybdenum mine.

1.2 PROJECT LOCATION

The Project is located in the coastal mountains of northwestern British Columbia. It is approximately 950 km northwest of Vancouver and 65 km northwest of Stewart, within 30 km of the British Columbia-Alaska border (Figure 1.2-1).

1.3 PROJECT OVERVIEW

The Project is located in two geographical areas: the Mine Site and Processing and Tailing Management Area (PTMA), connected by twin 23-km tunnels, the Mitchell-Treaty Twinned Tunnels (Figure 1.3-1). The Mine Site is located south of the closed Eskay Creek Mine, within the Mitchell, McTagg, and Sulphurets Creek valleys. Sulphurets Creek is a main tributary of the Unuk River, which flows to the Pacific Ocean. The PTMA is located in the upper tributaries of Teigen and Treaty creeks. Both creeks are tributaries of the Bell-Irving River, which flows to the Nass River and into the Pacific Ocean. The PTMA is located about 19 km southwest of Bell II on Highway 37.

The Mine Site will be accessed by a new road, the Coulter Creek Access Road, which will be built from km 70 on the Eskay Creek Mine Road. This road will follow Coulter and Sulphurets creeks to the Mine Site. The PTMA will also be accessed by a new road, the Treaty Creek Access Road, the first 3-km segment of which is a forest service road off of Highway 37. The Treaty Creek Access Road will parallel Treaty Creek.

Four deposits will be mined at the KSM Project—Kerr, Sulphurets, Mitchell, and Iron Cap—using a combination of open pit and underground mining methods. Waste rock will be stored in engineered rock storage facilities located in the Mitchell and McTagg valleys at the Mine Site. Ore will be crushed and transported through one of the Mitchell-Treaty Twinned Tunnels to the PTMA. This tunnel will also be used to route the electrical power transmission lines. The second tunnel will be used to transport personnel and bulk materials. The Process Plant will process an average of 130,000 tpd of ore to produce a daily average of 1,200 t of concentrate. Tailing will be pumped to the Tailing Management Facility from the Process Plant. Copper concentrate will be trucked from the PTMA along highways 37 and 37A to the Port of Stewart, which is approximately 170 km away via road.

The mine operating life is estimated at 51.5 years. Approximately 1,800 people will be employed annually during the Operation Phase. Project Construction will take about five years, and the capital cost of the Project is approximately US$5.3 billion.

2. Regulatory Framework

Whenever significant bedrock or unconsolidated material will be excavated or disturbed in British Columbia an ML/ARD program must be conducted so that, if necessary, prevention, mitigation and monitoring plans can be implemented.

The guiding BC provincial and federal principles for ML/ARD applicable to the long-term environmental management of the proposed KSM Project include:

- The prevention of ML/ARD. Prevention should be achieved through prediction, appropriate design, and effective implementation of appropriate mitigation strategies throughout the life of the proposed Project;
- The demonstration that the proposed mitigation strategies meet the environmental objectives for the proposed Project and are compatible with the proposed Project plan and site conditions;
- The ML/ARD potential is evaluated on a site-specific basis; and
- The requirement for water discharge into the receiving environment meets applicable Provincial and Federal water quality guidelines.

The federal Ministry of Environment's *Environmental Code of Practice for Metal Mines* sections 3 and 4 provide recommendations on predicting acidic drainage and metal leaching and creating environmental management plans for water and wastewater management at metal mines. In British Columbia, mining activities are regulated under the *Mines Act* (1996) and the Health, Safety and Reclamation Code for Mines in British Columbia (BCMEMPR 2008). Part 10 of the Health, Safety and Reclamation Code contains requirements for acid rock drainage and metal leaching prediction and prevention and reporting. ML/ARD prediction, prevention and mitigation in British Columbia are further guided by the following documents:

- Draft Recommended Methods for the Prediction of Metal Leaching and Acid Rock Drainage at Minesites in British Columbia (Price 1997).
- Policy for Metal Leaching and Acid Rock Drainage in British Columbia (BCMEM and BCMELP 1998)
- Guidelines for Metal Leaching and Acid Rock Drainage at Minesites in British Columbia (Price and Errington 1998);
- MEND Manual. Volume 3 – Prediction (MEND 2000);
- List of Potential Information Requirements in Metal Leaching/Acid Rock Drainage Assessment and Mitigation Work. MEND Report 5.10E (Price 2005); and
- Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials (Price 2009).

The general principles, policies, guidelines and recommended methods were applied to this assessment of the ML/ARD potential for the KSM Project.

3. Geology

3.1 GEOLOGICAL SETTING

The setting provided in this report is a summary of previously completed descriptions of the regional geology (Ditson, Wells, and Bridge 1995; Fowler and Wells 1995; Kirkham and Margolis 1995; Lechner 2008). A detailed description of the local lithologies, alteration, mineralization, and structures can be found in the 2012 Pre-Feasibility Study Update { Wardrop, 2012 #756}. The project scale geology is presented in Figure 3.1-1.

The Sulphurets District is located along the eastern side of the Coast Mountains, approximately 25km east of the Coast Plutonic Complex, a north-northwesterly trending belt of Cretaceous to Early Tertiary intrusions and high grade metamorphic rocks. The area lies near the western edge of the middle Jurassic to Cretaceous age Bowser Basin within the Stikine terrane, also known as Stikinia, which was possibly accreted to the North American continental margin in the Middle Jurassic period. Stikinia is interpreted as Triassic and Jurassic volcanic arcs resting on Palaeozoic basement (not present at site) and overlain by Jurassic basinal sedimentary rocks. The district is centred over the breached core of the northerly plunging McTagg anticlinorium, which exposes rocks of the upper Triassic Stuhini Group, unconformably overlain by lower Jurassic Hazelton Group rocks.

The upper Triassic Stuhini Group has two major subdivisions: (1) lower dominantly sedimentary turbidites and sandstones and (2) upper dominantly volcanic pillowed flows and volcaniclastic breccias.

The lower Jurassic Hazelton Group is inferred to represent a volcanosedimentary island arc and back-arc complex. The sedimentary sequence consists of a coarse basal sedimentary sequence overlain by a lower volcanic/volcaniclastic sequence, an upper felsic volcanic-pyroclastic unit (Mount Dilworth Formation), and an uppermost marine sedimentary sequence containing subaqueous mafic volcanic flows. The upper contact of the Hazelton Group is gradational with the Bowser Lake Group.

The middle Jurassic to middle Cretaceous Bowser Lake Group is a marine and continental clastic sedimentary succession consisting of basinal mudstone, sandstone and conglomerates that accumulated in a back-arc environment.

The Hazelton sedimentary sequence is intruded by a suite of porphyritic, early Jurassic (189 to 195 million years) rocks including alkali feldspar granite, quartz monzonite, seyenite, and granodiorite collectively referred to as the Mitchell Intrusions or Texas Creek Plutonic Suite. Below the Sulphurets and Mitchell thrust faults (STF and MTF), pre- and intra-mineral intrusives have historically been exploration targets.

The region has undergone a number of regional tectonic events starting with the accretion of Stikinia in the Middle Jurassic. The next major event was during the Late Jurassic through Late Cretaceous, possibly coinciding with the accretion of the Insular terranes west of the Coast Plutonic Complex. This latter event resulted in a widespread, generally east-verging fold and thrust belt affecting the Bowser Lake Group and older sequences.

3.2 DEPOSIT GEOLOGY

The following description of the deposit geology is taken from Savell (Savell 2012):

Kerr Zone

The Kerr deposit is a strongly deformed copper-gold porphyry, where copper and gold grades have been upgraded due to remobilization of metals during later and/or possibly syn-intrusive deformation. Alteration is the result of a relatively shallow, long lived hydrothermal system generated by intrusion of monzonite. Subsequent regional deformation along the Sulphurets thrust was diverted into Kerr area along pre-existing structures and altered rocks with low competency.

The mineralized area forms a mostly continuous, north-south trending and westerly dipping, irregular body at least 1700 meters long, and up to 200 meters thick. Higher grades are associated with crackled quartz stockwork, anhydrite veining, and chlorite alteration. It is enveloped by a schistose, pyrite rich phyllic alteration with low to moderate grades. Mineralization is open at depth and along strike.

Sulphurets Zone

The deposit is comprised of two distinct zones, Raewyn and Breccia Gold. The Raewyn Copper-Gold zone hosts mostly porphyry style disseminated chalcopyrite and associated gold mineralization in moderately quartz stockworked, chlorite-biotite-sericite-magnetite altered volcanics. The alteration and mineralization are centered on a narrow, apparently conformable body of porphyritic quartz monzonite. It has an apparent northeasterly strike and dips about 45 degrees to the north. It may be offset in en echelon style by several north-northeasterly trending vertical structures. The mineralization is open at down-dip and along strike to the southwest. The Breccia Gold zone hosts mostly gold bearing pyritic mineralization with minor chalcopyrite and sulfosalts in a K-feldspar-siliceous hydrothermal breccia that apparently crosscuts the Raewyn porphyry copper-gold deposit. It comprises altered intrusive clasts in a matrix of mainly silica and sulfides. Both zones have an intense phyllic overprint that nearly masks all earlier alteration phases.

Mitchell Zone

The Mitchell zone is exposed in Mitchell valley through an erosional window exposing the footwall of the Mitchell Thrust Fault. The zone is a moderately dipping, roughly tabular gold-copper deposit measuring approximately 1,600 meters along strike, 400 to 900 meters down dip, and at least 300 to 600 meters thick. It consists of a foliated, schistose or mylonitic zone of intensely altered and sulfide bearing rocks, with a variably distributed stockwork of deformed and flattened quartz veinlets. The schistosity generally follows an east-southeast direction, and dips moderately steep to the north. In general, the core area of mineralization has a moderate plunge to the north or northwest, and is lineated in a east-southeast direction.

Recent glacial melt back has provided exceptional surface exposure of a relatively fresh gold-copper porphyry system. A zone of intense quartz and sulfide veining ("High Quartz") forms resistant bluffs in Mitchell valley. However, the higher grade core area is mostly covered by talus and moraine west of the bluffs. Active oxidation and leaching of sulfides has produced prominent gossans and extensive copper sulfate precipitates at the surface.

SEABRIDGE GOLD
KSM PROJECT

Generalized Geology of the Kerr-Sulphurets-Mitchell Mine Project Area

Figure 3.1-1

Rescan™ Engineers & Scientists

The Mitchell zone is considered to lie within the spectrum of the gold-enriched copper porphyry environment. Metals, chiefly gold and copper (in terms of economic value), are generally at low concentrations, finely disseminated, stockwork or sheeted veinlet controlled, and pervasively dispersed over dimensions of hundreds of meters. Grades diminish slowly over large distances; sub-economic grades are encountered at distances of several hundreds of meters beyond the interpreted centre of the system. This is distinct from the Sulphurets and Kerr zones, where there are more abrupt breaks in grade due to higher structural complexity and juxtaposition of weak and moderate grade domains by faulting, both syn-mineral structures controlling breccia contacts, and post-mineral faulting and displacements. A property scale geological plan is presented on Figure 7.

Iron Cap Zone

The Iron Cap deposit is a separate but related mineralized system within the KSM district, and occurs structurally above the Mitchell deposit, in the panel of rocks between the Mitchell and Sulphurets thrust faults. It differs from the Mitchell deposit primarily in that much of the host rock is hydrothermally altered intrusive (porphyritic monzonite to diorite) rather than volcanics and sediments. The volcanics are mostly andesitic porphyry, generally similar to the main host of the Mitchell deposit. There is a high degree of silicification which overprints earlier potassic and chloritic alteration. Intense phyllic alteration and high density stockwork veining, which are pervasive at Mitchell are less pervasive at Iron Cap. Copper bearing zones at Iron Cap demonstrate higher grades than Mitchell, which is consistent with the intrusive setting and potassic alteration indicating a deeper and hotter environment.

Associated with the silicification are wide zones of hydrothermal brecciation, scattered meter-scale quartz-pyrite-chalcopyrite veins and centimeter-scale quartz-pyrite-chalcopyrite-sphalerite-galena-tetrahedrite veins that are interpreted to be superimposed on earlier stockwork and disseminated mineralization associated with the intrusion. Microscopic examinations of polished thin sections confirm that Iron Cap was also subjected to a post-mineral deformational event evidenced by widespread mylonitic textures. "Mylonite" and "Ultramylonite" are terms used as rock names in petrographic descriptions of several Iron Cap mineralized samples.

Generally intense silicification at the higher, eastern portions gives way to chloritization with some preserved k-spar alteration at depth and towards the west which correlates with increasing proportion of intrusive rock. Relative to Mitchell, stockwork veining is much weaker. There is a distinct overprint of structurally controlled, centimeter scale quartz-carbonate veins with chalcopyrite, galena, sphalerite, and tetrahedrite, but the distribution is not clear. It does not seem to effect the gold and copper distribution on a large scale, but at the vein scale there is often correlation. High silver values are generally associated with presence of galena and sphalerite.

4. Methods

4.1 PROGRAM DESIGN AND OBJECTIVES

This section describes the geochemical program designed to characterize and predict the potential for ML/ARD of the KSM Project deposit rock, tailing, and non-deposit rock. The geochemical program includes waste rock, pit walls, tailing, non-deposit or construction materials, and groundwater seep geochemistry. A summary of the design basis for characterization of ML/ARD potential is provided in Table 4-1.

Table 4-1. ML/ARD Characterization Program Design

Mine Component	Geochemical Questions	Data Needed	Methods
Waste Rock and Ore	ML/ARD potential	ABA	Core sampling, paste pH, acid potential, neutralization potential, solid-phase elemental analysis
		Mineralogy	Rietveld XRD and petrographic analysis
		Source of NP	Neutralization potential, Rietveld XRD, calcium and magnesium content, total carbon and inorganic carbon content
		Sulphur form interpretation	Sulphur species analysis, barium content
	Waste distribution (project scale)	Spatial variation of ML/ARD characteristics	Core sampling, paste pH, acid potential, neutralization potential, solid-phase elemental analysis
	Waste segregation (within a deposit)	Spatial variation of ML/ARD characteristics	Core sampling, composite continuous core samples, paste pH, acid potential, neutralization potential, solid-phase elemental analysis, ABA block model
	Development of site-specific ARD criteria	Rate of depletion of sulphides and acid neutralizing minerals	Humidity cells, field leach barrels
	Variability of characteristics within a deposit and between deposits	Lithological composition of waste rock over mine life	Core sampling, ABA and solid-phase elemental analysis, ABA block model
		Chemical composition of waste rock	Core sampling, ABA and solid-phase elemental analysis, ABA block model
	Onset of acidic conditions	Rate of depletion of sulphides and acid neutralizing minerals	Humidity cells and lag-time calculations
	Contact water chemistry	Leaching rates under non-acidic and acidic conditions	Humidity cells, sub-aerial drip columns
		Site-specific water quality data	Field leach barrels, groundwater seeps
Pit Walls	Variability of characteristics within a deposit and between deposits	Lithological composition of pit walls over mine life	ABA block model and mine plan
	Release of potential parameters of concern	Leaching rates under non-acidic and acidic conditions	Humidity cells
	Chemistry of runoff	See waste rock program	See waste rock program

Table 4-1. ML/ARD Characterization Program Design (completed)

Mine Component	Geochemical Questions	Data Needed	Methods
Tailing	ML/ARD potential	ABA	Metallurgical testing, paste pH, acid potential, neutralization potential, solid-phase elemental analysis
		Mineralogy	Rietveld XRD, petrographic and QEMSCAN analyses
		Particle size analysis	Wet sieving and laser diffraction
		Source of NP	Neutralization potential, Rietveld XRD, calcium and magnesium content, total carbon and inorganic carbon content
		Sulphur form interpretation	Sulphur species analysis, barium content
	Variability of characteristics within a deposit and between deposits	Source of tailing (deposit)	Metallurgical testing, kinetic testing of composite samples, mine plan
	Onset of acidic conditions	Rate of depletion of sulphides and acid neutralizing minerals	Humidity cells, aging tests, subaqueous columns
	Chemistry of tailing management facility ponds and porewater	Leaching rates under non-acidic and acidic conditions	Humidity cells, aging tests, subaqueous columns
		Leaching rates under sub-aerial and sub-aqueous conditions	Humidity cells, aging tests, subaqueous columns
Non-deposit Material	ML/ARD potential	ABA	Overburden and outcrop sampling, paste pH, acid potential, neutralization potential, solid-phase elemental analysis
		Surface-soluble leaching from non-deposit or construction materials	Overburden and outcrop sampling, shake-flask extraction of overburden, and meteoric water mobility procedure of non-deposit rock

The overall objective of the ML/ARD prediction program for the KSM Project was to obtain a correlation between the geological and geochemical data that can be used for:

- waste and water management planning; and
- environmental effect assessment.

The ML/ARD prediction program was developed using a phased approach. As a result, this 2008-2012 cumulative baseline reports the results of the sampling and testing from 2008 until April 2012 and incorporates results reported in the 2008 baseline report (Rescan 2009). The cut-off date for sampling and analytical data inclusion in this report is July 2012 for all data sets except the groundwater seeps which include all 2012 analytical data.

A summary of samples collected and laboratory testing performed for ML/ARD prediction for the Project is provided in Appendix 4.1-1. Only data that passed QA/QC are presented in this baseline; historical data from before 2008 did not meet standards and is presented in appendix 4.1-2.

4.1.1 Waste Rock and Pit Walls

To achieve the waste management planning objective, 2,030 samples were collected from diamond drill holes of waste rock and potential pit wall material. Table 4.1-1 outlines the development of the sampling program.

Table 4.1-1. Summary of Waste Rock and Pit Wall Sampling Program

Deposit	2008	2009	2010	2011	2012	Total
Kerr	17	71	78	0	139	305
Sulphurets	87	79	132	0	135	433
Mitchell	277	462	189	0	8	936
Iron Cap	0	0	50	149	157	356
Total	381	612	449	149	439	2030

Between 2008 and 2010, deposit sampling focussed on the ML/ARD prediction of waste rock and pit wall rock of the Mitchell, Sulphurets, and Kerr Deposits. The selection of samples was based on primary lithologies used by Seabridge geologists for core logging of the KSM deposits. However, based on consultation with Seabridge geologists in early 2009, sampling selection was changed to include primary alteration types. The rationale for changing to this approach, particularly below the Mitchell Thrust Fault (MTF), was based on the intensity of alterations that obscured and inhibited the identification of primary protoliths, and close associations between alteration types, mineralization, and gold and copper ore grades. In 2011 and 2012, the focus of the deposit sampling for the ML/ARD prediction program was on the Sulphurets and Iron Cap deposits to more thoroughly characterize the potential pit walls of these deposits. Additionally, the Sulphurets Canyon Zone underwent exploration drilling in 2011 to expand the boundaries of the deposit. Since early 2012 selection of samples has been based on the geological block model codes as provided by Seabridge.

Humidity cells and drip columns containing waste rock were initiated in 2008, 2009, and 2010.

4.1.2 Tailing

Several metallurgical test programs were completed for the KSM Project from 2007 to 2010. Further details regarding these metallurgical programs are contained in Section 16 of the Pre-Feasibility Study Update ({Wardrop, 2012 #756}) and will be included in the 2012 update to the Pre-Feasibility Study.

A comprehensive ML/ARD prediction program was developed and initiated for the KSM Project tailing. This program was developed in conjunction with comprehensive metallurgical testing being carried out for Seabridge. The tailing-specific objective of the KSM ML/ARD prediction program was to characterize the geochemical variability and behaviour of tailing products that would be generated by the Process Plant and included:

- Mitchell RougherRougher tailing;
- Mitchell RougherRougher tailing coarse;
- Mitchell RougherRougher tailing fine;
- Mitchell Cleaner (sulphide/pyrite) tailing;
- Mitchell RougherRougher/Sulphide tailing combined at a 9:1 ratio - equivalent to the relative contributions of Rougher and cleaner tailing to the TMF;
- Mitchell/Sulphurets RougherRougher tailing and tailing composite;

- Mitchell/Kerr RougherRougher tailing and tailing composite; and
- Iron Cap RougherRougher tailing and tailing composite.

The tailing combinations reflect that given the size and duration of projected mining of the Mitchell deposit, Mitchell tailing geochemistry will be dominant compared to the other deposits. Humidity cell tests, subaqueous tests and aging tests were also included in the KSM tailing ML/ARD prediction program.

4.1.3 Non-deposit Material

This section describes the geochemical program designed to characterize and predict the potential for ML/ARD of the KSM construction material.

During construction of the KSM Project, clearing and excavation of surficial and bedrock materials will be required. Additionally, borrow sources of unconsolidated overburden will potentially be required for dams, roads, infrastructure footings and foundations and other features. Samples of overburden, outcrop, and drill core were collected to assess the ML/ARD potential of the construction material and to identify potential sources for borrow material.

A summary of the non-deposit sampling program performed for ML/ARD prediction for the Project is provided in Table 4.1-2.

Table 4.1-2. Summary of Non-Deposit Sampling Program

Location	Overburden		Rock	
Sample Type	Drill Hole	Grab	Drill Hole	Grab
Coulter Creek Access Road (CCAR)		1		47
Kerr Haul Rd		4		
Mitchell Diversion Tunnel (MDT)				13
Mitchell Pit		4		27
Mitchell Rock Storage Facility (MRSF)	16	8		
McTagg Diversion Tunnel (MTDT)				5
McTagg Rock Storage Facility (MTRSF)		2		
Mitchell-Teigen Tunnel (MTT)				15
Sulphurets Laydown Area	1		4	
Sulphurets Pit				14
Teigen Access Road (TAR)				13
Treaty Creek Access Road (TCAR)		3		6
Treaty Creek Spur Road				15
Ted Morris Valley		5		
Teigen Creek Valley		6		
Processing and Tailing Management Area (PTMA)	2		3	
Water Storage Facility (WSF)	6	3		
Sub-total	25	36	7	155
Total = 223				

The overburden grab sample set was tested for grain size distribution, ABA including surface rinse pH on whole sample and separately on the minus 2 mm fraction, paste pH, sulphur species, Sobek

neutralization potential (NP) and carbon species, as well as solid-phase elemental analyses (ICP and whole rock) and shake flask leach extraction tests on a subset of samples. The drill core and outcrop samples were tested for ABA (paste pH, sulphur species, Sobek NP, carbon species) and solid-phase elemental analysis.

4.1.4 Groundwater Seep Geochemistry

Naturally-occurring groundwater seeps within the Project area were sampled in order to assess:

- the variability in aqueous chemistry associated with groundwater seeps derived from various lithologies and alteration types; and
- the geochemical loading contribution to the local watershed.

It is reasonable to assume that a given unit of water in a seep will have a greater residence time in contact with bedrock than water from humidity cells and field barrels. In this regard, the seeps provide an opportunity to evaluate site-specific geochemistry at a larger field scale than both humidity cells and field barrels, and may be more representative of full scale near equilibrium mine drainage aqueous concentrations.

Naturally-occurring seeps occur at the Kerr Deposit, Sulphurets Deposit, Mitchell Deposit, McTagg Creek (location of McTagg Rock Storage Facility), and Ted Morris Creek Valley (outside of the KSM Project footprint but a north-flowing tributary of Sulphurets Creek near the confluence of Mitchell Creek with Sulphurets Creek). The Ted Morris Creek Valley seeps represent a reference location with little mineralization. At the Kerr, Sulphurets, and Mitchell Deposits, the seeps represent groundwater that has reacted with potential ore, waste rock and pit wall material and discharges into the local watershed. The seeps at the Kerr and Mitchell Deposits discharge where there is moderate to intense deposit weathering and the development of a young gossan at the surface. The Mitchell Deposit was exposed due to glacial recession within the last 50 years. Glacier studies conducted for Seabridge indicate that the Mitchell Glacier has retreated about 800 m and decreased about 100 m in thickness since 1982 (Rescan 2010{Rescan, 2010 #692}). As a result of the recent glacial recession, the Mitchell Deposit gossan is quite young and remains highly reactive. Copper and iron staining were observed on outcrop samples at several locations within the Sulphurets Deposit. In general, the Sulphurets Deposit is located at a high elevation in a zone of groundwater recharge.

Sampled KSM groundwater seeps included:

- Kerr Deposit seeps: 5;
- Sulphurets Deposit seeps:1;
- Mitchell Deposit seeps: 23;
- McTagg Creek seeps: 3; and
- Ted Morris seeps: 5

4.2 FIELD SAMPLING

4.2.1 Deposit Sampling

From 2008 to 2012, a total of 305 drill core samples from the Kerr Deposit, 433 drill core samples from the Sulphurets Deposit, 936 drill core samples from the Mitchell Deposit, and 356 drill core samples from the Iron Cap deposit were collected for the purpose of ML/ARD predictions. Drill core intervals

samples were typically 1.0 or 2.0 metres length; however, where a drill hole had poor recovery or sampling for laboratory assays had removed intervals of interest, adjustments were made accordingly.

The summary of the samples tested for ABA and solid-phase elemental analysis is presented in Table 4.2-1.

Table 4.2-1. Summary of KSM Samples Tested for ABA and Elemental Analysis

Classification	Number of Samples Kerr Deposit	Number of Samples Sulphurets Deposit	Number of Samples Mitchell Deposit	Number of Samples Iron Cap Deposit
Ore				
Not-PAG	18	59	42	6
PAG	109	103	421	153
Sub Total Ore Samples	127	162	463	159
Waste				
Not-PAG	38	185	91	24
PAG	140	85	382	172
Sub Total Waste Samples	178	270	473	196
Total of Samples	**305**	**433**	**936**	**356**
Number of drill holes	22	40	102	40

Forty samples from 29 drill holes were selected for laboratory humidity cells testing to assess the primary reaction rates under aerobic weathering condition, including the rates of metal leaching, acid generation, and acid neutralization.

Samples of split drill core and outcrop material of different lithologies were collected for field kinetic testing. The material sampled represents:

- Material from the proposed Mitchell Pit highwall above the MTF;
- A composite of different alteration types intersecting the pit wall from the proposed Mitchell Pit from below the MTF; and
- Different alteration types for the Mitchell, Sulphurets and Kerr Deposits: intermediate argillic (IARG), silica flooding, pervasive silicification (SIL), silicification due to hornfelsing, silica flooding (SIH), chlorite alteration (CL) and potassic alteration (KP).

Samples of split drill core of material from the proposed Mitchell Pit highwall above the MTF were also used for sub-aerial column testing.

4.2.2 Non-deposit Sampling

A total of 223 non-deposit samples were collected from overburden and rock in the KSM Project area for assessment of ML/ARD potential. The sampled overburden areas included those that may potentially be disturbed, exposed, or excavated during proposed mining activities.

The overburden samples consist of 36 grabs of unconsolidated material (e.g. gravel, colluvium, and alluvium), and 25 drill core samples. The rock samples consist of 155 rock grabs and seven samples from drill holes.

4.2.3 Groundwater Seep Sampling

The location of the seeps in the Kerr Deposit, Sulphurets Deposit, Mitchell Deposit, McTagg Creek Valley, and Ted Morris Creek Valley are shown in Figures 4.2-1 to 4.2-5, respectively. Photos of Mitchell and Kerr Deposit seeps are shown in Plates 4.2-1 to 4.2-3.

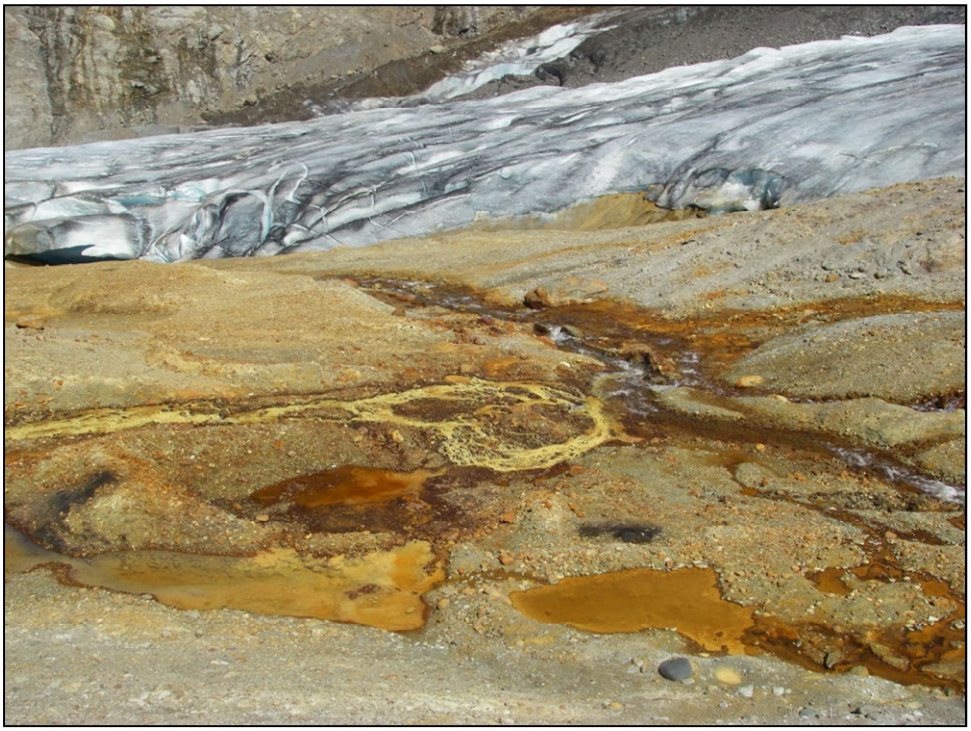

Plate 4.2-3. Area of Seep MS_G, July 2010.

When compared to humidity cells and field leach barrels, the seep water has reacted with a larger mass of rock for a longer period of time. In this regard, the seep water is expected to be a closer representation to the aqueous geochemistry that can be expected from the weathering of waste and pit wall rock over the life of the mine. The chemical composition of seep water will be influenced by the type and mass of reactive material encountered as well as the order in which different reactive materials are encountered (Morin and Hutt 1997). The seep water is a composite of water that has taken multiple flow paths where scales of reaction from mesoscale (path) and microscale (pore) reactions occur.

Groundwater seeps in and around the KSM Project area were sampled up to four times in 2009 (July, August, September, and October), up to three times in 2010 (June, July, and August), and four times in 2012 (July, August, September, and October). Data for two seeps collected in 2011 at the toe of the Mitchell glacier are included in the stream dataset in the KSM Project: 2007-2011 Surface Water Quality Baseline (Rescan 2012a).

4.2.3.1 Seep Flow Measurements

Flow rates were measured for seeps in September and October of 2009 and in July 2010 using a Swoffer meter to measure flow velocity directly or using a container of known volume and a stopwatch to estimate the rate of discharge.

4.2.3.2 Seep Water Sampling

Seeps were sampled as close to the source as possible to reduce the amount of atmospheric interaction. The parameters pH, dissolved oxygen (DO), conductivity, temperature and oxygen-reduction potential (ORP) were measured in the field with an YSI Multi-Parameter System (Model #556) that was calibrated daily. The values were recorded once they had stabilized. Aqueous samples were obtained by syringe and filtered with a 0.45 micron cellulose-nitrate filter and preserved with nitric acid for dissolved metals. Non-filtered samples were obtained for total metals, total organic carbon (TOC) and general

parameters (including pH, conductivity, and major anions). Total metals and TOC samples were preserved in the field with nitric and hydrochloric acids, respectively. All samples were refrigerated or stored on ice in a cooler and were shipped to a certified lab within one week of collection. Duplicate samples were obtained at a minimum 10% frequency.

4.3 STATIC TESTS

4.3.1 Sampling

Composites were prepared where required according to instructions provided. Rock samples were crushed to -9.52 mm. Each sample was mixed by passing through a ½ inch splitter box and recombined. A 200 g split was made and pulverized in a ring pulverizer to 80% -200 mesh. Splits of the pulverized sample were then submitted for analysis.

4.3.2 Acid-Base Accounting

ABA was conducted according to the Sobek NP procedure. The procedure is outlined in Price (2009): Approximately 0.5 g of sample was treated with 1 or 2 drops of 25% hydrochloric acid (HCl) to determine its "fizz rating", which determined the volume and normality of HCl to be used in the titration. A 2.0 g sample was then treated with the appropriate volume and normality of HCl by gentle heating until reaction was complete, followed by the addition of carbon-dioxide free de-ionized water and a one minute boiling period. The solution was covered tightly to cool, and then titrated with the appropriate normality of sodium hydroxide solution until the pH reading remained at 7.0 for at least 30 seconds.

4.3.2.1 Paste pH and Rinse pH

Paste pH was determined according to the procedure in Price (2009). Typically the sample was pulverized to <250 µm size or smaller and distilled water added at approximately 1:2 water to solid weight ratio. In the field the pulverized material frequently was not as fine as <250 µm. Paste pH was conducted on both lithified (drill core, bedrock, mine wall materials) and weathered non lithified samples. If samples had undergone weathering and sulphide oxidation prior to analysis, then paste pH values less than 6.0 were measured and indicated acidity was previously generated and net acidity stored within the sample.

Rinse pH was conducted on a dry sieve sorted <2 mm particle size fraction with no particle comminution. Distilled water was added at approximately 1:1 water to solid weight ratio.

4.3.2.2 Sulphur Species

A wide range of sulphide minerals have been identified in the deposit rock that have been subject to various levels of oxidation ranging from nil to extensive that result in numerous sulphur species being present. The sulphur species that occur include: sulphide-sulphur (e.g., pyrite), leachable sulphate-sulphur (e.g., gypsum or anhydrite), and non-leachable sulphate-sulphur (e.g., barite or elemental sulphur). Total-sulphur is an analytical measure that represents the sum of all sulphur species present.

Total-sulphur was determined by a Leco induction furnace method (Price 2009). In the Leco method, the furnace was operated at or above 1650^{o}C, and all sulphur species were volatilized. Leco systems used chemical filters to ensure accurate analysis and protect the instrument from damage. The sulphur dioxide generated from the sample was measured with an infrared (IR) detector. The total-sulphur content of the sample was calculated by the instrument and reported.

Sulphide-sulphur was determined directly by Leco induction furnace method (Price 2009) after the sulphates were removed by heating the sample in sodium carbonate solution. The insoluble carbonates

and sulphides were separated from the sulphates by filtration. The sulphide residue was subsequently washed free of carbonate solution and analyzed by a Leco analyzer.

Sulphide-sulphur was determined indirectly by subtraction of sulphate-sulphur species from total-sulphur.

Sulphate-sulphur was determined using two different procedures (Price 2009): hydrochloric acid (HCl) leach and carbonate leach.

In the HCl leach method, the sample was exposed to heated HCl for 30 minutes. Silica and acid-insoluble material were removed by filtration and ferric iron was reduced to ferrous iron by the addition of hydroxylamine hydrochloride. The sulphate in the resulting filtrate was then precipitated with barium chloride in a dilute HCl medium. The barium sulphate precipitate was filtered, ignited, weighed, and calculated as %S.

In the carbonate leach method, the sample was boiled with a sodium carbonate solution for 30 minutes. Any insoluble materials were removed by filtration and ferric iron was reduced to ferrous iron by the addition of hydroxylamine hydrochloride. The sulphate in the resulting filtrate was then precipitated with barium chloride in a dilute HCl acid medium. The barium sulphate precipitate was filtered, ignited, weighed, and calculated as %S.

4.3.2.3 Neutralization Potential

All samples, except the Treaty Creek Access Road samples, were analyzed by the Sobek NP.

Sobek "bulk neutralization potential" (NP) is based on digestion of the rock sample in a hot (near boiling) acid (HCl) bath. The amount of acid consumed was determined by back titration with sodium hydroxide (NaOH) to a pH endpoint of 7.0.

The estimation of unavailable NP, i.e the maximum NP that corresponds to a paste pH below 6.0, was used as a standard practice (Price 2009). Bulk Sobek NP is used in the estimation of the unavailable NP because there is a strong correlation between Bulk Sobek NP and calculated NP indicating that most of the NP of the deposits is provided by calcium carbonate minerals. Based on the relationship between paste pH and Bulk Sobek NP values, up to 15 kg $CaCO_3$/t of measured NP could be associated with acidic paste pH values. This value was derived from the complete 2008 to 2012 KSM Project static test database. The data indicate that the unavailable NP of 15 kg $CaCO_3$/t is valid for the Kerr, Mitchell, and Iron Cap Deposits. An unavailable NP of 8 kg $CaCO_3$/t is valid for the Sulphurets Deposit. The Rock Storage Facilities (RSFs) will be composed of a mix of alteration types and rocks from several deposits and therefore the conservative estimate of unavailable NP is applied across all deposits model codes. The neutralization potential was adjusted by this estimate of unavailable NP to calculate an adjusted neutralization potential (Adjusted NP or AdjNP; Price, 2009). The mean Adjusted NP values predictably decrease by approximately 15 kg $CaCO_3$/t; however, where neutralization potentials were below 15 kg $CaCO_3$/t, the adjusted neutralization potential was set to a default value of 0 kg $CaCO_3$/t.

The site-specific unavailable NP for the non-deposit materials at the KSM Project was determined to be:

- 8 kg $CaCO_3$/t in PTMA non-deposit samples;
- 9 kg $CaCO_3$/t in CCAR non-deposit samples; and
- 15 kg $CaCO_3$/t in Mine Site tunnels, Mitchell Pit, Sulphurets Laydown Area, and Sulphurets Pit non deposit samples.

4.3.2.4 Carbon Species

Total-carbon was determined by a Leco induction furnace method (Price 2009). In the Leco method, the furnace was operated at or above 1650°C, and all carbon species were volatilized. The carbon dioxide generated from the sample was measured with an infrared (IR) detector. The total carbon content of the sample was calculated by the instrument and reported.

Inorganic Carbon (CO_2) was determined by coulometry (Price 2009). A prepared sample (0.01 – 0.03 g) was acidified in a heated reaction vessel to evolve inorganic carbon as carbon dioxide. Carbon dioxide-free air was then used to move the evolved carbon dioxide into the CO_2 coulometer. In the coulometer, CO_2 was quantitatively absorbed and reacted with monoethanolamine to form a titratable acid, which caused the colour of the solution to fade. A photodetector was used to measure the change in colour as percent transmittance, and from this value µg of carbon dioxide was calculated.

4.3.2.5 Calculated Parameters

The list of the ABA calculated parameters is presented in Table 4.3-1.

Table 4.3-1. Table of Acid Base Accounting (ABA) Calculated Parameters

Parameter	Units	Calculation
Sulphide-sulphur ($S(S_2)CALC$)	%	%S(S2)CALC = total-sulphur - sulphate-sulphur
Barium-bound sulphate-sulphur ($S\text{-}BaSO_4$)	%	%$S\text{-}BaSO_4$ =Ba (ppm) x 0.0001 x 32.06/137.37
S-del (any analytically unaccounted for-sulphur forms)	%	S-del = %Total-Sulphur - %sulphide-sulphur - %leachable sulphate-sulphur(HCl leach) - %barium bound sulphate-sulphur
Total Acid Potential (TAP)	kg $CaCO_3$/t	TAP = %Total-Sulphur x 31.25
Sulphide Acid Potential (SAP)	kg $CaCO_3$/t	SAP = (%Sulphide-Sulphur + %del-Sulphur) x 31.25
Adjusted NP	kg $CaCO_3$/t	AdjNP = Sobek NP- Unavailable NP
Organic carbon (C-del-calc)	%	C-del-calc = % Total carbon - % Inorganic carbon
Total NP (CaNP-TTL)	kg $CaCO_3$/t	CaNP-TTL = %C x 10 x 100.09/12.01
Inorg NP (CANP-INORG)	kg $CaCO_3$/t	CaNP-Inorg = %CO_2 x 10 x 100.09/44.01
CaNP (CANP-CA)	kg $CaCO_3$/t	CANP-CA = (%Ca x 10000) x (100.09/40.08)/1000
CaMgNP (CANP-CAMG)	kg $CaCO_3$/t	CANP-CAMG = (%Ca+%Mg) x 10000) x (100.09/40.08)/1000
Total Net Neutralization potential (TNNP)	kg $CaCO_3$/t	TNNP = NP - TAP
Adjusted TNNP	kg $CaCO_3$/t	TNNP = Adjusted NP - TAP
Sulphide Net Neutralization Potential (SNNP)	kg $CaCO_3$/t	SNNP = NP - SAP
Adjusted SNNP	kg $CaCO_3$/t	SNNP = Adjusted NP - SAP
Inorganic Carbon Net Neutralization Potential (ICNNP)	kg $CaCO_3$/t	ICNNP = Inorganic CaNP - TAP
Total Net Potential Ratio (TNPR)	unitless	TNPR = Sobek NP / TAP
Adjusted TNPR	unitless	TNPR = Adjusted Sobek NP / TAP
Sulphide Net Potential Ratio (SNPR)	unitless	SNPR = Sobek NP / SAP
Adjusted SNPR	unitless	SNPR = Adjusted Sobek NP / SAP
Inorganic Carbon Net Potential Ration (ICNPR)	unitless	ICNPR = Inorganic CaNP / TAP

4.3.3 Whole Rock and Solid-Phase Elemental Analysis

The multi-element concentrations in the ML/ARD samples were measured by Inductively Coupled Plasma - Mass Spectrometry (ICP-MS) analysis after strong four-acid digestion and by X-ray fluorescence spectroscopy (XRF) whole-rock analysis.

For total metals analysis, a prepared sample was digested with perchloric, nitric, hydrofluoric and hydrochloric acids. The residue was topped up with dilute hydrochloric acid and analyzed by inductively coupled plasma-atomic emission spectrometry. Following this analysis, the results were reviewed for high concentrations of bismuth, mercury, molybdenum, silver and tungsten and diluted accordingly. Samples meeting this criterion were then analyzed by inductively coupled plasma-mass spectrometry. Results were corrected for spectral inter-element interferences.

Some sample duplicates were analyzed for total metals by using aqua regia (3:1 mixture of hydrochloric and nitric acid) digestion followed by ICP-MS analysis. These results will not be further presented in this report.

Whole-rock analysis was performed by Lithium Metaborate Fusion followed by XRF Analysis for major oxides.

4.3.4 Mineralogy

The mineralogical analyses were performed by X-ray diffraction (XRD) analyses, petrographic examinations, and quantitative evaluation of minerals by scanning electron microscopy (QEMSCAN) analyses (tailing only).

The XRD analyses were carried out at the Department of Earth & Ocean Sciences, University of British Columbia (UBC) using a Bruker D8 Focus Bragg-Brentano diffractometer. The samples were reduced to the optimum grain size for quantitative X-ray analysis (<10 μm) by grinding under ethanol in a vibratory McCrone Micronising Mill for seven minutes. The X-ray diffractograms were analyzed using the International Centre for Diffraction Database PDF-4 and Search-Match software by Siemens (Bruker). X-ray powder-diffraction data of the samples were refined with Rietveld program Topas 4.2 (Bruker AXS). The results of quantitative phase analysis by Rietveld refinements represent the relative amounts of crystalline phases normalized to 100%.

The samples were forwarded to Vancouver Petrographics, where a 30 μm thick polished thin section of each sample was prepared. Petrographic descriptions were performed by Mineral Services Canada Inc. using a Nikon Eclipse E400 microscope equipped with transmitted and reflected light.

The mineralogical composition in tailing samples was also determined at G&T Metallurgical Services Ltd by using particle mineral analysis (PMA) techniques by QEMSCAN. Spectra for each mineral present, as well as back scatter micrographs for mineral phases of interest were also detected. The analysis was performed on unsized samples, but provided useful quantitative measurements of mineral content.

4.3.5 Particle Size Analysis

The particle size distribution of the tailing samples submitted for humidity cell tests was determined by wet sieving method (Mitchell tailing) and by laser diffraction method (Mitchell/Kerr Rougher, Mitchell/Sulphurets Rougher, and Iron Cap Rougher tailing) using the Malvern Mastersizer 2000 at the N.B. Keevil Institute of Mining Engineering, UBC.

4.4 KINETIC TESTS

Kinetic and leachate tests were designed to encompass water-to-rock ratios of 0.2 to 3.3 and water-material contact times of 1 to 120 days. This range represents the natural ranges found in the various RSF and TMF project components.

4.4.1 Humidity Cells

Humidity kinetic tests were performed according to the MEND Procedure (Price 2009). The waste rock humidity cells were made from acrylic tubing, with an 8 inch (20 cm) height and 4 inch (10 cm) diameter for a 1 kg sample. The cells had a fixed base plate with a leachate drainage hole fitted with a tubing nipple. Approximately one inch (2.5 cm) above the base, a perforated plexiglass plate was fitted to support the sample. The plate was covered with 6 layers of nylon mesh to prevent loss of fines while still allowing upward flow of air and downward flow of leachate. A hose nipple was fitted to the side wall below the support plate for the dry and humid air inlet. The cells were equipped with a removable lid with a central hole for an air outlet. The air inlets and leachate drains were equipped with suitable pinch valves. Tailing humidity cells are shorter and wider to allow timely fluid flow through the finer grained material.

Waste rock samples were crushed to 70 percent of <6 mm. Tailing material was added to the humidity cell without any additional crushing. One kilogram was split out from each sample and placed in a cell. For the initial leach cycle, 750 mL of nanopure water was added with the leachate drain closed. After one hour the cell was drained, the volume recorded and the leachate submitted for analysis.

Each cell was operated on a seven day cycle. For the first three days dry air was passed through the cell. Then for the next three days humidified air was passed through the cell from a humidifier. On the seventh day of the cycle the airflow was disconnected and the leaching cycle was repeated using 500 mL of nanopure water. The leachate volume was recorded and the sample submitted for analysis.

Analysis of the leachate included pH, conductivity, acidity, alkalinity, sulphate, and dissolved metals. The pH was measured using an Orion pH meter; conductivity was determined using a Fisher Scientific conductivity meter; acidity was determined by titration with base to an end point of either pH 4.5 (free acidity) or pH 8.3 (total acidity); alkalinity was determined by titration with an acid to an end point of pH 4.5.

Metal analysis on the leachate was conducted on a preserved sample by ICP-MS. Standard procedures were followed (APHA-AWWA-WEF 1998). Table 4.4-1 presents the detection limits for the metal analyses method.

A total of 40 laboratory humidity cells were initiated and operated to assess the ML/ARD properties of potential waste rock and pit wall rock from the Kerr, Mitchell, Sulphurets, and Iron Cap deposits of the proposed KSM Project. Eight of the humidity cells were initiated in February 2009, 26 were initiated in February and March 2010, and six were initiated in February 2011.

The humidity cells were constructed at ALS Environmental in Burnaby, BC, SGS Canada Inc. in Burnaby, BC and Maxxam Analytics in Burnaby, BC to provide temporal data to aid the prediction of future drainage chemistry from waste rock and pit wall rock.

Tables 4.4-2 present a summary of the KSM humidity cells characteristics. For the purpose of this discussion, the humidity cells have been divided by deposit and position relative to the MTF, and are further subdivided by model code (Section 4.6, M. Lechner, pers. comm.). The number of cycles of humidity cell operation presented here ranges from 57 to 163 weekly cycles.

Table 4.4-1. Detection Limits for the Metal Analyses Method in KSM Humidity Cells Leachate

Dissolved Metal	Realized Detection Limits	Dissolved Metal	Realized Detection Limits
Aluminum	0.01	Mercury	0.000001-0.01

The rationale for the selection of humidity cell samples was to achieve variability of leachate in PAG material of different lithologies and alterations. Table 4.4-3 present a summary of the KSM humidity representativity. The humidity cell leach rates represent the majority of the 2012 block model codes.

Original construction of the humidity cells was based on lithology and alteration codes from exploration drill logs, and the definition of model codes was updated in the ABA block model generated in 2011 and 2012 (Section 4.6).

4.4.2 Sub-Aerial Drip Columns

In March 2009, four laboratory columns were constructed using Mitchell Deposit drill core samples of the same deposit lithologies as were used for field leach barrels 1 to 4. The columns were operated for 88 weeks and terminated on November 24, 2010.

The purpose of these columns was to determine if aqueous concentrations would be obtained under laboratory controlled conditions that would approach and provide a comparison of aqueous concentrations obtained from full-scale site-specific field conditions in the field leach barrels. Waste rock from the Mitchell Deposit will dominate the chemistry of the RSF; therefore, only Mitchell Deposit material was selected for this test.

Table 4.4-3. KSM Waste Rock Representivity of Humidity Cells

4.4.2.1 Sample Selection

In September 2008, four field kinetic barrels, Barrels 1 through 4, were constructed. These barrels are composites of split drill core of different lithologies: porphyritic monzonite or syenite, andesite, undifferentiated sediments and volcanics of unknown protolith. The material in these barrels represents material from the proposed Mitchell Pit highwall above the MTF. Material was chosen as an intermediate step between humidity cells and field kinetic barrels for scaling purposes for high wall Subsamples of composited material used to create the four field kinetic barrels were collected and used to construct four laboratory sub-aerial drip columns.

4.4.2.2 Methodology

The laboratory sub-aerial drip column dimensions were 12.8 cm inside diameter by 38.0 cm high and filled with 5.0 kg of drill core crushed to 0.635 cm with minimal fines.

The columns were operated by maintaining a constant feed reservoir of 3,000 mL of deionized water. During each weekly cycle, deionized water was dripped at a constant rate into the top of the columns. The quantity of water recovered each week from the bottom of the column varied from a minimum of 2,680 to a maximum of 3,000 mL. Once sufficient leachate was collected for physical measurements and analysis, the remaining leachate was recirculated back into the feed reservoir. Therefore the leachate chemistry reflects a cumulative loading from successive cycles of flushing through the rock in the column. It should be noted that a small amount of dilution occurred each cycle as the feed reservoir was replenished with additional deionized water to make up the feed solution to 3,000 mL.

The amount of leachate used for weekly analyses was dependent on the leachate volume recovered and the parameter suite analyzed. Initially, weekly analysis of a full suite of parameters was conducted. From week 33 to week 59, a full suite of parameters was analyzed weekly, after which full analysis was reduced to a monthly frequency, with intermediate weeks consisting of pH and conductivity measurements. The changes in analytical frequency were made in response to column geochemical behaviour: either steady trends with no significant changes or continuing temporal changes.

4.4.3 Field Leach Barrels

Eighteen field leach barrels were constructed at the KSM Camp to provide field kinetic test data for the prediction of future mine drainage chemistry that includes primary mineral weathering, secondary mineral precipitation and dissolution (Price 1997), from waste rock and pit walls in the proposed KSM Project mine site. The barrels represent scaled-up leach tests that are conducted under site-specific field conditions (Morin and Hutt 1997). In the barrels, temperatures and water-rock ratios are generally lower than laboratory tests and exhibit seasonal fluctuations. The barrels contain more material (100's of kg) than corresponding laboratory humidity cells (1 kg) and rely on meteoric water flushing to generate leachate. The material in the barrels is coarser (minus 2.54 cm) than in the humidity cells (minus 0.63 cm), resulting in a lower reactivity per unit volume due to decreased surface area.

The barrels were constructed using either 200 L (Barrels 1-13, 18) or 100 L (Barrels 14-17) HDPE barrels with a 5.08 cm PVC outlet pipe and 19 L leachate collection buckets (Plate 4.4-1). Field kinetic barrels 1-17 were filled with split drill core or rock outcrop samples as follows:

- Barrels 1-4: Mitchell Deposit lithologies from above the Mitchell Thrust Fault;
- Barrel 5: Mitchell Deposit pit wall composite from below the Mitchell Thrust Fault;
- Barrels 6-13, and 17: Alteration types for the Mitchell, Sulphurets and Kerr Deposits; and
- Barrels 14-16: Highwall outcrop material from Mitchell and Sulphurets Deposits.

Plate 4.4-1. Photo of initial field kinetic barrel set-up.

Barrel 18 is a blank (or control) barrel that was constructed in September 2010 to quantify the chemistry of meteoric input water and ensure that the barrel construction materials are not contributing significantly to the leachate chemistry. An Iron Cap field barrel was not established due to the relatively small volume of waste rock expected to be produced from the Iron Cap deposit compared to the other three deposits due to block caving. Waste rock chemistry will be dominated by waste rock from the Mitchell deposit.

Barrels 1 through 4 were constructed in September of 2008. These barrels are composed of split drill core of different lithologies: porphyritic monzonite or syenite, andesite, undifferentiated sediments and volcanics of unknown protolith. The material in these barrels represents the rock that will be exposed in the proposed Mitchell Pit (MP) highwall above the Mitchell Thrust Fault. Barrel 5 was constructed in August 2009 and contains split drill core representing a composite of different alteration types intersecting the pitwall of the proposed Mitchell Pit (MP) below the Mitchell Thrust Fault. Due to the obscuring of the primary protolith lithologies in the deposits by intense alteration, seven field kinetic barrels were constructed from split drill core samples of different alteration types in September 2009. These barrels are composed of: intermediate argillic, silica flooding, pervasive silicification, silicification due to hornfelsing, silica flooding, chlorite alteration and potassic alteration. Barrels 13-17 were constructed in September 2010 with material obtained from rock outcrop from the Mitchell and Sulphurets Deposits. The material in Barrels 13 and 17 represent weathered “gossan” of intermediate argillic or phyllic alteration-type from the Mitchell Deposit. Barrels 14-16 are composite outcrop samples of Sulphurets, Mitchell North and Mitchell South highwall rock, respectively.

Table 4.4-4 summarizes the construction date, lithologies, primary alteration type and height of material contained within each field kinetic barrel. In all cases, the source of material in the barrel is denoted with the first letter of the deposit from which it was obtained. For example, Barrel 7 contains intermediate argillic altered material from the Mitchell Valley and is labelled M-IARG.

Barrels 1 to 12 were modified in September 2010 in order to increase the reactivity of the split drill core material (i.e., increase (reactive) surface area) following the advice provided by an external peer reviewer. Prior to modification, the material in the barrels was split core predominantly ranging in length from approximately 10 to 50 cm but also containing “fines” collected from the drill core boxes when sampled. The modifications consisted of:

- physically breaking the drill core splits into smaller sizes (i.e., minus 2.5 cm);
- adding air ports consisting of three sections of 5.08 cm slotted PVC well screen to ensure material at depth in the field kinetic barrels was well oxygenated;
- securing geotextile to the inlet of the outlet pipe to stop fine particulate matter escaping; and
- placing a layer of silica sand on the bottom of the field kinetic barrel to the top of the inlet pipe to raise the drill core material out of any standing water and covering the sand with geotextile.

A photo of the barrel reconfigurations is shown in Plate 4.4-2.

During the construction of the barrels, solid samples were obtained for ABA and solid-phase elemental concentration analysis consisting of ICP-MS elemental and whole rock oxide analyses. The number of samples (core intervals) obtained, ranged from a minimum of nine samples for Barrel 3, M-SEDS to a maximum of 57 samples from Barrel 7, M-IARG. Static testing of samples for barrels constructed in September 2010 was not completed.

Table 4.4-4. KSM Field Leach Barrels Characteristics

	Construction Date	Zone	Material	Lithology	Alteration	Deposit Code	Barrel Size	Material Height (cm)

Plate 4.4-2. Photo of field kinetic barrel reconfiguration.

The barrel leachate was sampled monthly from July to November in 2009, June to September in 2010, and June to October in 2011. Barrel leachate will be sampled from June to October 2012. The data from July 2009 to October 2011 are presented here. Subsequent results will be reported separately and used to verify and confirm these results and predict mine site drainage and aqueous chemistry at a field scale.

The parameters pH, dissolved oxygen (DO), conductivity, temperature and oxygen-reduction potential (ORP) were measured in the field with an YSI Multi-Parameter System (Model #556) that was calibrated daily. The values were recorded once they had stabilized. Aqueous samples were obtained by syringe and filtered with a 0.45 micron cellulose-nitrate filter and preserved with nitric acid for dissolved metals. Non-filtered samples were obtained for total metals, total organic carbon (TOC) and general parameters. Total metals and TOC samples were preserved in the field with nitric and hydrochloric acids, respectively. Samples were refrigerated or stored on ice in a cooler and were shipped to a certified lab in Vancouver within one week of being collected. Duplicate samples were obtained at a minimum 1 in 10 frequency.

4.4.4 Aging Tests

Tailing aging tests, where the tailing and its supernatant were allowed to age over 30 to 120 days, were carried out on the Mitchell Rougher, Rougher/Sulphide and Sulphide tailing. The tailing combinations reflect that given the size and duration of projected mining of the Mitchell deposit, Mitchell tailing geochemistry will be dominant compared to the other deposits.

The supernatants were analysed at days 0, 7, 14, 30, 60, 90, and 120 for conductivity, pH, acidity (as $CaCO_3$), alkalinity total (as $CaCO_3$), bromide, chloride, fluoride, nitrite, nitrate, sulphate, and dissolved metals.

4.4.5 Subaqueous Columns

Subaqueous column tests were undertaken on the following tailing samples with the purpose of evaluating the geochemical behaviour of tailing submerged under water:

- Mitchell Rougher;
- Mitchell Rougher/Sulphide;
- Mitchell Sulphide;
- Mitchell/Kerr Rougher; and
- Mitchell/Sulphurets Rougher.

The subaqueous columns consisted of cylindrical Plexiglas™ plastic cells (12.5 cm inside diameter by 48.3 cm long). A five kilogram sample of tailing solid of each type described above was placed in individual subaqueous columns and covered by 14 cm of de-ionized water at all times. The placed tailing solids created a column approximately 22.9 cm to 25.4 cm high. The column was loosely covered with a Plexiglas™ plastic plate that had a 0.6 cm hole in the middle for the weekly addition of make-up de-ionized water to replace the volume of water sampled. No air flow was forced over the cover water.

During each weekly sampling cycle, 250 ml of the pore water was extracted through a valve situated at the base of the columns, using a vacuum. This procedure took between one and four hours depending on the particle size of the tailing sample. In addition, 250 ml of cover water was collected using a second valve located approximately 0.6 cm above the tailing solid top. After the weekly water sampling was completed, approximately 500 ml of de-ionized water was slowly added to the top of the column in order to keep the surface water cover constant at 14 cm of above the tailing solids. The weekly sampling procedure and sample analyses were the same as for the tailing humidity cells. The following analyses were conducted:

- Conductivity, pH, acidity (as $CaCO_3$), alkalinity total (as $CaCO_3$), bromide, chloride, fluoride, nitrite, nitrate, sulphate; and
- Dissolved metals: aluminum, antimony, arsenic, barium, beryllium, bismuth, boron, cadmium, calcium, chromium, cobalt, copper, iron, lead, lithium, magnesium, manganese, mercury, molybdenum, nickel, phosphorus, potassium, selenium, silicon, silver, sodium, strontium, thallium, tin, titanium, uranium, vanadium, zinc.

A photograph of a typical subaqueous column test setup is shown in Plate 4.4-3.

4.5 LEACHATE TESTS

Several leachate tests were performed on samples from the KSM Project. Leachate tests include:

- soluble constituents analysis (as part of elemental analysis) in the non-deposit overburden and rock by:
  - Leachate extraction using the shake flask extraction (SFE);
  - Selective-dissolution analysis by sequential extraction using the Meteoric Water Mobility Procedure (MWMP); and
- Net Acid Generation (NAG) procedures on the deposit waste rock.

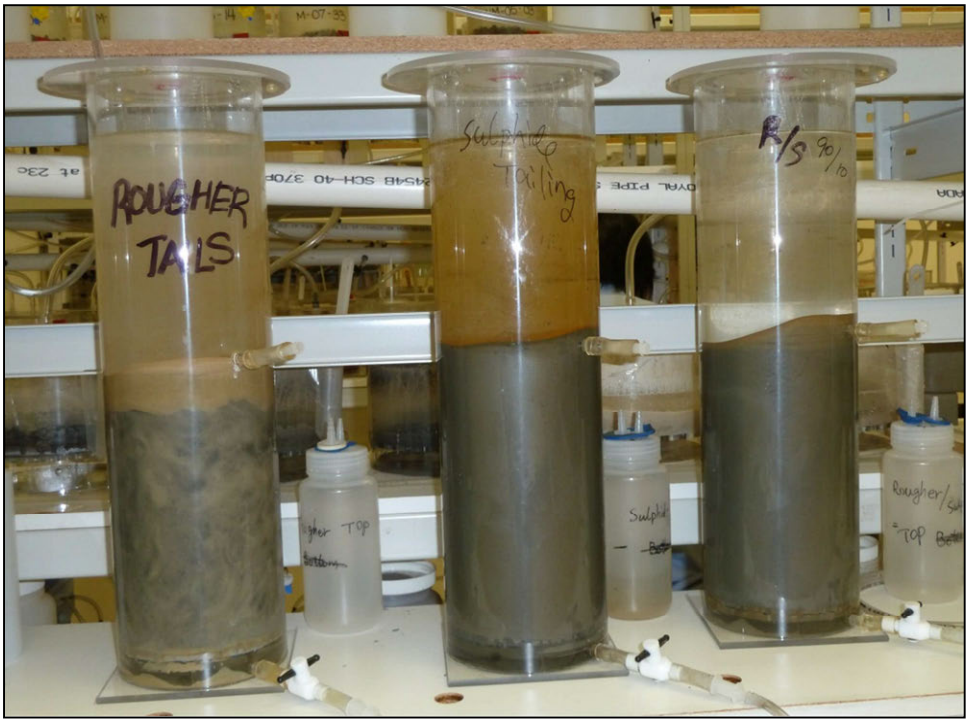

Plate 4.4-3. Photo of subaqueous column kinetic test configuration.

4.5.1 Leachate Extraction

The analysis for soluble constituents was carried out by leachate extraction using the SFE procedure (Price 2009). The shake flask extraction tests were undertaken using a 3:1 water to solids ratio and shaken for 24 hours

The purpose of the MWMP is to evaluate the potential for dissolution and mobility of certain constituents from a non-deposit rock sample by meteoric water. The procedure consists of a single-pass column leach over a 24 hour period using a mine rock sample to extraction fluid (effluent) ratio of 1:1. The extraction fluid is Type II reagent grade water.

4.5.2 NAG Procedures

NAG tests use hydrogen peroxide (H_2O_2), a strong oxidizing agent capable of rapidly oxidizing sulphide minerals, to assess whether a sample is capable of neutralizing the potential acidity.

A preliminary two-cycle sequential NAG test (Price 2009) was performed on 84 samples of deposit rock from the Kerr, Sulphurets, and Mitchell Deposits to determine the volumes of hydrogen peroxide needed to reach a complete sulphide oxidation. A single addition NAG test (Price 2009) was carried out on a sub-set of 49 samples using the volumes of hydrogen peroxide determined by the two-cycle tests. The results from the modified single addition NAG were used to identify potentially acid-forming (PAF) and not acid-forming (NAF) material and the percentage of metals associated with sulphide-mineral phases.

In the two-cycle NAG tests, 2.5 g of sample was reacted two times with 250 mL aliquots of 15% hydrogen peroxide. At the end of each stage, the sample was filtered and the solution was used for measurements of NAG pH and NAG acidity. The resulting solid residue was rinsed with deionized water to remove any excess of unreacted hydrogen peroxide. The rinsed solid residue was then filtered and the liquor was discarded. The NAG test was then repeated on the solid residue.

In the modified single addition NAG test, 2.5 g of sample was reacted with a determined volume of 15% hydrogen peroxide. The hydrogen peroxide volumes ranged from 500 mL to 3000 mL.

In both the two-cycle and single addition procedures:

- The NAG liquor was analyzed for pH, conductivity, sulphate, acidity, fluoride (SIE), chloride (IC), and dissolved metals (ICP-MS).
- The NAG solid residue was analysed for total-sulphur (by Leco), sulphide-sulphur (Na_2CO_3 Leach method), and total metals using four-acid digestion followed by ICP-MS ICP.

4.6 GEOLOGIC AND ABA BLOCK MODEL

Acid-base accounting (ABA) block models for the KSM Project were constructed by Mike Lechner, of Resource Modeling Inc., in 2010 and 2011. The ABA block models were constructed with data collected from relatively widely spaced drill holes from materials thought to be representative of "ore", "low-grade", and "waste". The resolution of individual model blocks is 25 m x 25 m x 15 m. An ABA block model is not required to characterize the ML/ARD potential of waste material. However, the block model allows for mapping of large zones of material that have similar ML/ARD potential and can allow segregation in the waste rock schedule. Planning the waste rock schedule based on the ABA block model allows for effective modelling of hauling and dumping costs of material that can be segregated. A general outline of the method used to generate the ABA block model is given below (M. Lechner [pers. comm.]):

> *"The ABA models are based on samples that were selected by Rescan employees which were collected from existing drill hole assay pulps. Basic descriptive statistics were tabulated for sulphide acid potential (SAP), adjusted neutralization potential (NPADJ), total sulphur, and sulphide sulphur based on block model codes, alteration types, degree of mineralization, and stratigraphic position relative to major thrust faults.*
>
> *The models were constructed using three distinct methods: 1) direct assignment of ABA values to blocks "pierced" by ABA samples; 2) two-pass inverse distance estimation methods and 3) assignment of ABA values based on average values calculated by rock/alteration/mineralization type. Individual model blocks which were pierced by an ABA sample were assigned neutralization potential (NP) and sulphide acid potential (SAP) values from those samples and flagged as being estimated and off limits for subsequent estimation methods. After that ABA assignment was completed, a two pass inverse distance estimation method was implemented. The first pass used a 100 m x 100 m x 60 m search ellipse to locate eligible ABA samples. A minimum of one sample was required with a maximum of eight samples used to interpolate NP and SAP values. Blocks estimated by this method were flagged as being estimated and not subjected to subsequent estimates. The second estimation pass used a 200 m x 200 m x 120 m search ellipse with the same sample selection used for the first pass. Strict block/sample matching was used in both inverse distance estimation passes. This means that blocks of a certain rock type could only be estimated by samples with the same rock type. Unique search ellipse orientations were used for the Kerr, Sulphurets, and Mitchell zones [including Iron Cap]. A minimum of one sample was required, with a maximum of eight samples allowed with no more than two samples from each drill hole. An inverse distance weighting power of two was selected.*
>
> *For blocks beyond 200 m of ABA sample data, class average values were assigned to blocks based on rock, alteration, or mineralization codes. The average values for NP*

and SAP for these static samples are influenced by mineralization intensity. Typically, as gold and/or copper grades increase NP values decrease and SAP values increase. Commingling mineralized and unmineralized ABA samples has provided a certain degree of conservatism since most of the mineralized material will be processed and not sent to a waste rock disposal area.

After the estimate and assignment of block ABA values was completed, a simple ratio (SNPRA) was calculated. This ratio is based on neutralization potential (NPADJ) divided by acid potential (SAP). Blocks with ratios greater than 2.0 were considered to be acid neutral while all other blocks are considered to have the potential of being acid generating."

Table 4.6-1, below, lists the different rock model codes that are used in this report. These are the same codes that Seabridge and engineering design firms will be using, allowing for more efficient cross-discipline communications. Included in the table are the 2011 block codes and a linkage between the two model code versions. This linkage is not definitive but represents the most common conversion pathway between the two versions of the block model.

4.7 METHODS USED TO CALCULATED DEPLETION TIMES AND ARD ONSET

The leachate concentrations and initial concentrations in the solid phase were used to calculate the depletion rates of sulphide, bulk Sobek NP, and carbonate NP to estimate the depletion times and the onset of ARD. The leachate concentrations have reached a steady state, therefore the data from the last 10 weekly cycles are used for the calculation of the mean production rates.

Sulphide depletion time was calculated as follow:

$$Sulphide\ Depletion\ \ (Years) = Remaining\ Sulphide\ (mmol/kg) / Mean\ Rate\ of\ Sulphur\ Depletion\ per\ week\ (based\ on\ last\ 10\ weeks) * 52$$

$$Remaining\ Sulphide\ (mmol) = Initial\ Sulphide\ (Sulphide + Del)(mmol) - Total\ Sulphur\ Lost\ (mmol)$$

$$Mean\ Rate\ of\ \ Sulphur\ Depletion\ per\ week\ (based\ on\ last\ 10\ weeks)\ (mmol/kg) = Sum\ of\ Sulphur\ Production\ Rate\ over\ last\ 10\ weeks/10\ weeks$$

$$Total\ Sulphur\ Lost\ (mmol/kg) = Sum\ of\ Sulphur\ Production\ Rate(mmol/kg)$$

$$Sulphate\ Production\ Rate\ (mg/kg) * (32.06/96.06)/1000 = SulphurProduction\ Rate\ (g/kg)/32.06 * 1000 = SulphurProduction\ Rate(mmol/kg)$$

Bulk Sobek NP and Carbonate NP depletion time was calculated as follow:

$$Bulk\ Sobek\ NP\ Depletion\ \ (Years) = (Remaining\ Bulk\ Sobek\ NP\ ((mmol/kg)) /(Mean\ Rate\ of\ \ NP\ Depletion\ per\ week\ (based\ on\ last\ 10\ weeks)\ ) * 52$$

$$Remaining\ Bulk\ Sobek\ NP\ (mmol) = Initial\ Adjusted\ Bulk\ Sobek\ NP\ (Bulk\ Sobek\ NP\ as\ Ca)(mmol) - Total\ \ NP\ Lost\ (mmol)$$

$$Carbonate\ NP\ Depletion\ \ (Years) = (Remaining\ Carbonate\ NP\ ((mmol/kg)) /(Mean\ Rate\ of\ NP\ Depletion\ per\ week\ (based\ on\ las\ 10\ weeks)\ ) * 52$$

5. Deposit Waste Rock Results

5.1 STATIC TESTS

This section describes the geochemical characteristics of the KSM Project waste rock and its potential for ML/ARD based on the geochemical static test analysis results.

This report includes all the static tests results from 2008 to July 2012 including the previous static results presented in the KSM 2008 Baseline Report (Rescan 2009). The ABA and solid-phase elemental analysis were conducted on a total of 166 samples from the Kerr Deposit, 371 samples from the Sulphurets Deposit, 928 samples from the Mitchell Deposit and 356 samples from the Iron Cap deposit.

The distribution of the samples by deposits was:

- 305 samples from Kerr Deposit (127 ore samples and 178 waste rock samples);
- 432 samples from Sulphurets Deposit (162 ore samples, 270 waste rock samples);
- 936 samples from Mitchell Deposit (463 ore samples, 473 waste rock samples); and
- 356 samples from the Iron Cap Deposit (160 ore samples, 196 waste rock samples)

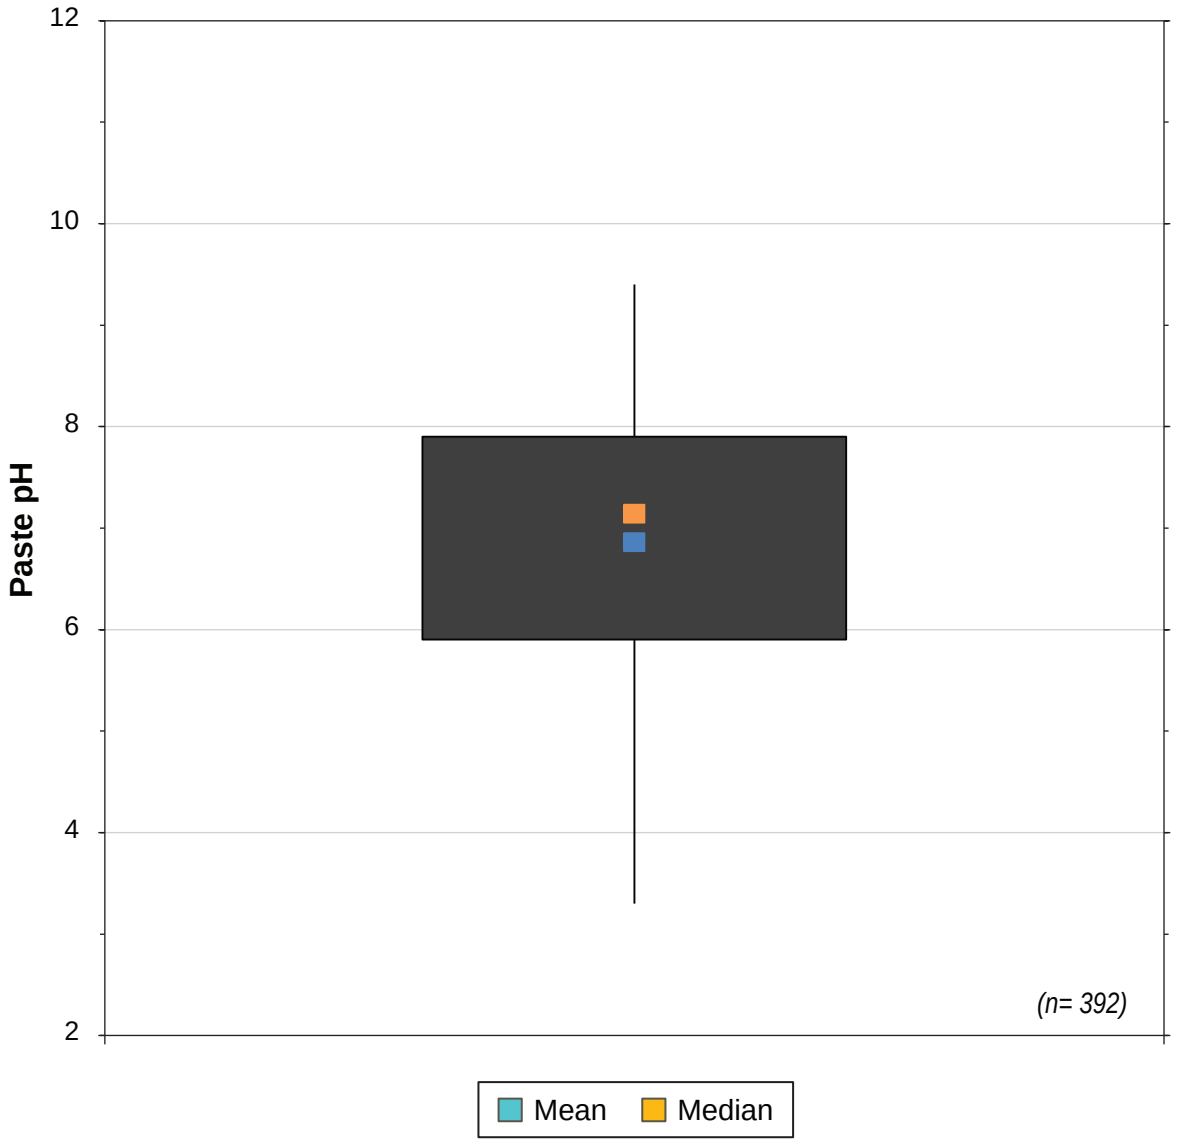
5.1.1 Kerr Deposit

The ABA and solid-phase elemental analyses were conducted on a total of 305 samples from the Kerr Deposit (293 drill core samples and 12 pulp samples from drill core samples). Detailed results of the static tests and statistical summaries for the Kerr Deposit are presented in Appendix 5.1-1.

The ABA and solid-phase elemental analyses were conducted on a total of 166 samples from the Kerr Deposit. Detailed results of the static tests and statistical summaries for the Kerr Deposit are presented in Appendix 5.1-1.

5.1.1.1 Paste pH

The paste pH of 305 Kerr Deposit samples ranged from a minimum of 3.3 to a maximum of 9.6, with a mean of 7.4 and a median of 7.7 (Figure 5.1-1).



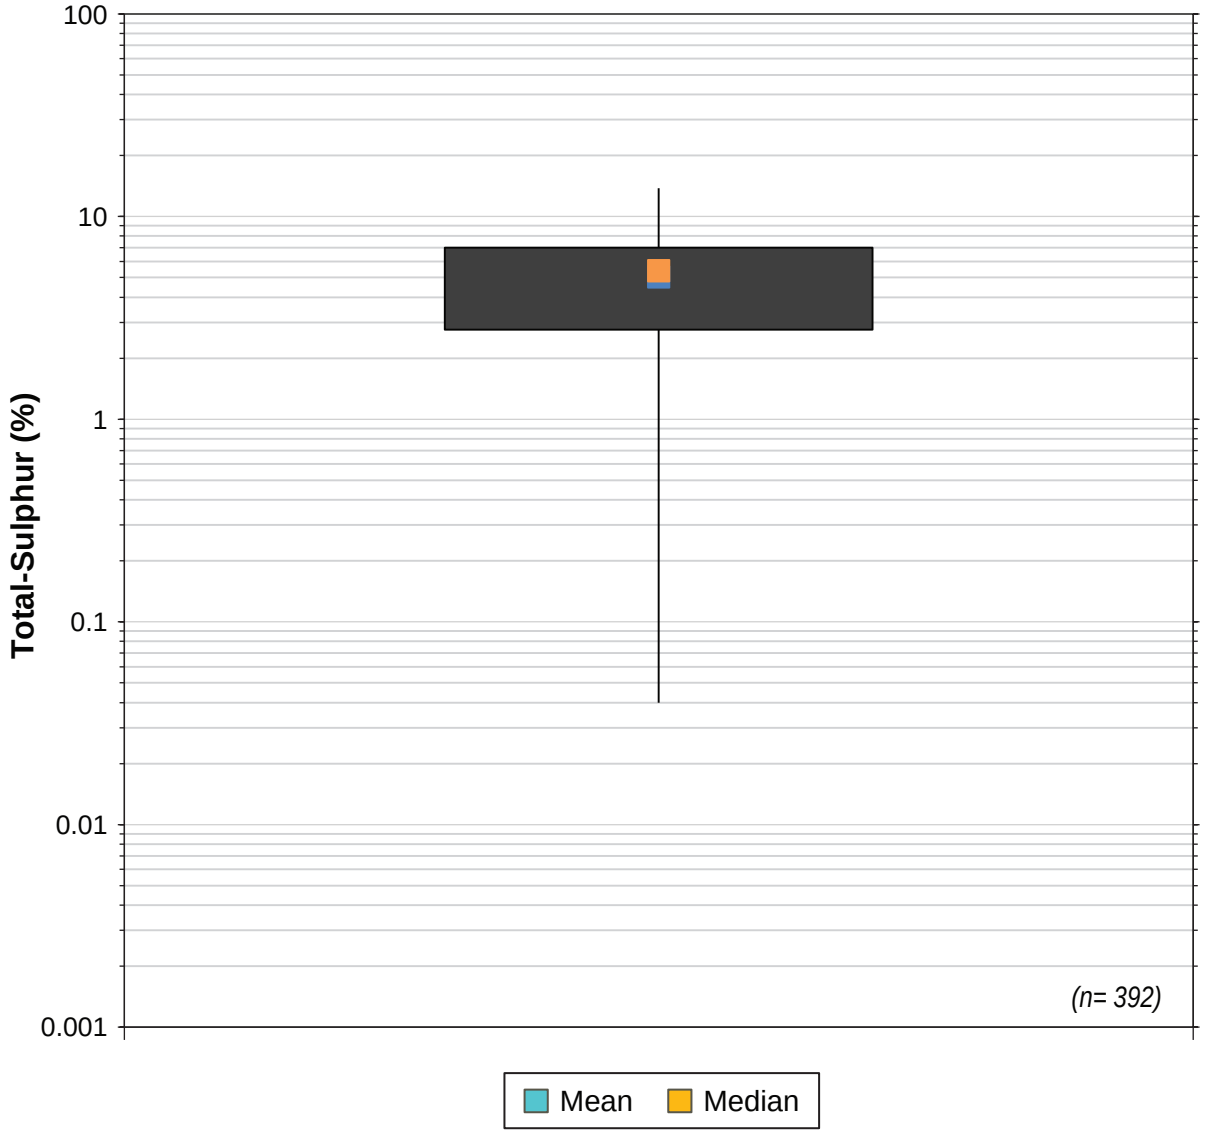
Static test results of the Kerr Deposit drill core samples revealed that 18% of samples had a paste pH less than 6.0 at the time of laboratory testing, indicating sulphide oxidation and net acid generation had already occurred.

5.1.1.2 Sulphur Species

A statistical summary of the total-sulphur concentrations for the Kerr Deposit is shown in Figure 5.1-2. The total-sulphur content results of 305 samples from the Kerr Deposit ranged from a minimum of 0.01% to a maximum of 13.81%, with a mean of 4.53% and a median of 4.73%.

A statistical summary of the sulphide-sulphur concentrations for the Kerr Deposit is shown in Figure 5.1-3. The sulphide-sulphur content of 239 samples from the Kerr Deposit ranged from a minimum of 0.02% to a maximum of 10.3%, with a mean of 3.64% and a median of 3.57%.

The relationship between sulphide-sulphur and total-sulphur concentrations for the Kerr Deposit is shown in Figure 5.1-4.



Note: 25th to 75th percentile is represented by the shaded box.

Sulphide-Sulphur versus Total-Sulphur in the Kerr Deposit

Figure 5.1-4

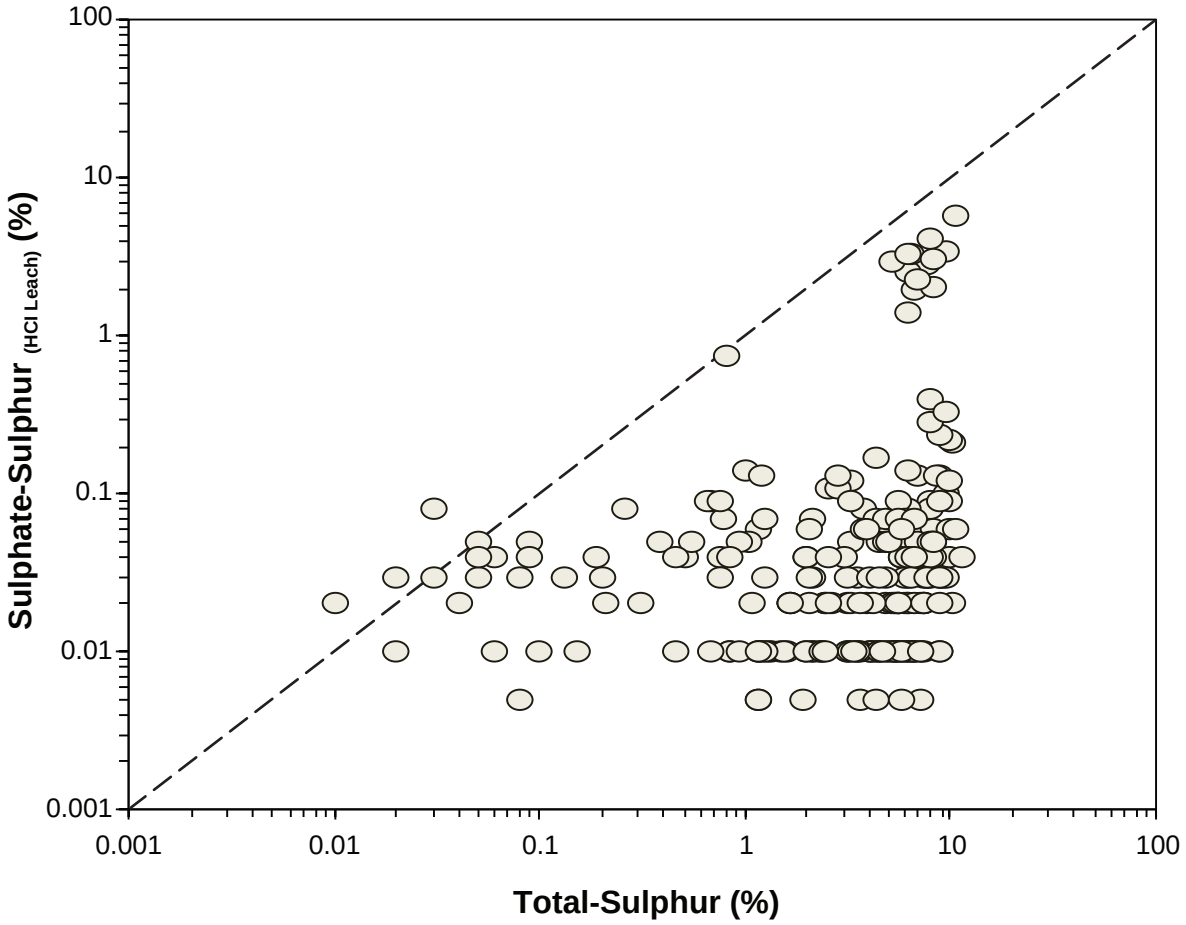
Rescan™ Engineers & Scientists

In general, there is a strong relationship between sulphide-sulphur and total-sulphur for total-sulphur concentrations greater than 0.3%. However, the results show a weak correlation in a few samples. Moderately soluble sulphate-sulphur species such as gypsum were reported by XRD analysis in the Kerr Deposit. Figure 5.1-5 shows the relationship between acid-soluble sulphate-sulphur and total-sulphur concentrations indicating that there are high concentrations of acid-soluble sulphate-sulphur present in some of the Kerr Deposit samples.

5.1.1.3 Neutralization Potential

A statistical summary of the Bulk Sobek neutralization potential (NP) values for the Kerr Deposit is shown in Figure 5.1-6. The Sobek NP values for 305 samples from the Kerr Deposit range from a minimum of -1 to a maximum of 482 kg $CaCO_3$/t, with a mean of 53 kg $CaCO_3$/t and a median of 20 kg $CaCO_3$/t.

Based on the relationship between paste pH and Bulk Sobek NP values shown in Figure 5.1-7, up to 15 kg $CaCO_3$/t of measured NP could be associated with acidic paste pH values. This value was derived from the complete 2008 to 2012 KSM Project static test database. The data indicate that the unavailable NP of 15 kg $CaCO_3$/t is valid for the Kerr Deposit. The Rock Storage Facilities (RSFs) will be composed of a mix of alteration types and rocks from several deposits and therefore the conservative estimate of unavailable NP is applied across all deposits model codes. The neutralization potential was adjusted by this estimate of unavailable NP to calculate an adjusted neutralization potential (Adjusted NP).



The correlation between Bulk Sobek NP and Inorg NP is shown in Figure 5.1-8. Below the unavailable NP line, the Inorg NP shows a poor correlation to Sobek NP, suggesting unavailable Sobek NP is comprised of a mixture of carbonate and non-carbonate minerals. Above the unavailable NP line of 15 kg $CaCO_3$/t, the Inorg NP shows a strong correlation to Sobek NP, suggesting that most of the available Sobek NP in the Kerr Deposit occurs as carbonate minerals. Therefore the Inorg NP can be used for estimating the available NP in the Kerr Deposit.

A plot of a Calcium CaNP (Ca CaNP), assuming that the elemental calcium is present as calcite, versus Sobek NP is shown in Figure 5.1-9. Below the unavailable NP line, the Ca CaNP shows a poor correlation to Sobek NP indicating a measurable portion of Ca CaNP is not providing neutralization or is unreactive. This poor correlation indicates a greater proportion of calcium from non-carbonate mineral phases. Above the unavailable NP line, the Ca CaNP shows a strong correlation to Sobek NP, indicating that most of the available Sobek NP in the Kerr Deposit occurs as calcium carbonate minerals. Therefore the Ca CaNP can be used for estimating the available NP in the Kerr Deposit.

A plot of a Calcium-Magnesium CaNP (CaMg CaNP), assuming that the elemental calcium and magnesium are present as dolomite, versus Sobek NP is shown in Figure 5.1-10. The correlation between CaMg CaNP and Sobek NP was poorer than for Ca CaNP, indicating that a measurable portion of CaMg CaNP is not providing neutralization or is unreactive (Figure 5.1-10). This poor correlation indicates that magnesium occurs predominantly in non-carbonate magnesium-bearing mineral phases. Therefore the CaMg CaNP cannot be used reliably for estimating the available NP in the Kerr Deposit.

5.1.1.4 Sulphide Net Potential Ratios

A statistical summary of the adjusted SNPR for the Kerr Deposit is shown in Figure 5.1-11. The adjusted SNPR for 305 samples from the Kerr Deposit range from a minimum of 0.01 to a maximum of 515, with a mean of 6 and a median of 0.041.

Statistical Summary of Kerr Deposit Adjusted Net Potential Ratios

Figure 5.1-11

Rescan™ Engineers & Scientists

The ABA screening criteria (Price, 1997) were applied. Seventy seven percent of the samples have adjusted SNPR<1, indicating that they are potentially acid generating (PAG). From those samples 132 samples (56%) were assigned SNPR default values of 0.01, indicating that the samples had NP values equal to or lower than 15 kg$CaCO_3$/t. Samples with an adjusted SNPR of 0.01 are predicted to have rapid onset of acidic conditions. Four percent of the samples have adjusted SNPR between 1.0 and 2.0, indicating they are possibly acid generating (UPAG) and 18 % of the samples have adjusted SNPR>2, indicating that they are not potentially acid generating (not-PAG).

The relationship between paste pH and adjusted SNPR of Kerr Deposit samples is shown in Figure 5.1-12. Samples with adjusted SNPR of 0.01 were associated with both acidic and neutral/alkaline paste pH, indicating that part of the samples are in an advanced stage of acid generation (acidic samples) and part of the samples are in the early stage of acid generation (no acidic samples).

The relationship between sulphide-sulphur and adjusted SNPR of Kerr Deposit samples is shown in Figure 5.1-13. The samples with a combination of sulphide-sulphur greater than 0.1% and an adjusted SNPR<2 are the most likely net ARD generating samples in the long term.

5.1.1.5 Whole Rock and Solid-phase Elemental Analysis

The multi-element concentrations in the ML/ARD samples from the Kerr Deposit were measured by ICP-MS analysis after strong four-acid digestion and by XRF whole-rock analysis. The results are found in Appendix 5.1-1.

Most of the Kerr Deposit rock was comprised of oxide-equivalents of SiO_2 and Al_2O_3, which is consistent with the dominant presence of quartz, feldspar minerals, and other aluminosilicate minerals in Kerr Deposit rock based on XRD analysis. Also consistent with the general mineralogy, there were lesser but still significant amounts of Fe_2O_3, K_2O, CaO, MgO, and Na_2O.

The solid-phase concentrations of each element were compared with concentrations found in the earth's crust (crustal abundance) in order to determine which elements occur in anomalously high concentrations (Price 1997). Any elemental concentration higher than three times its crustal abundance was considered an anomalously high concentration.

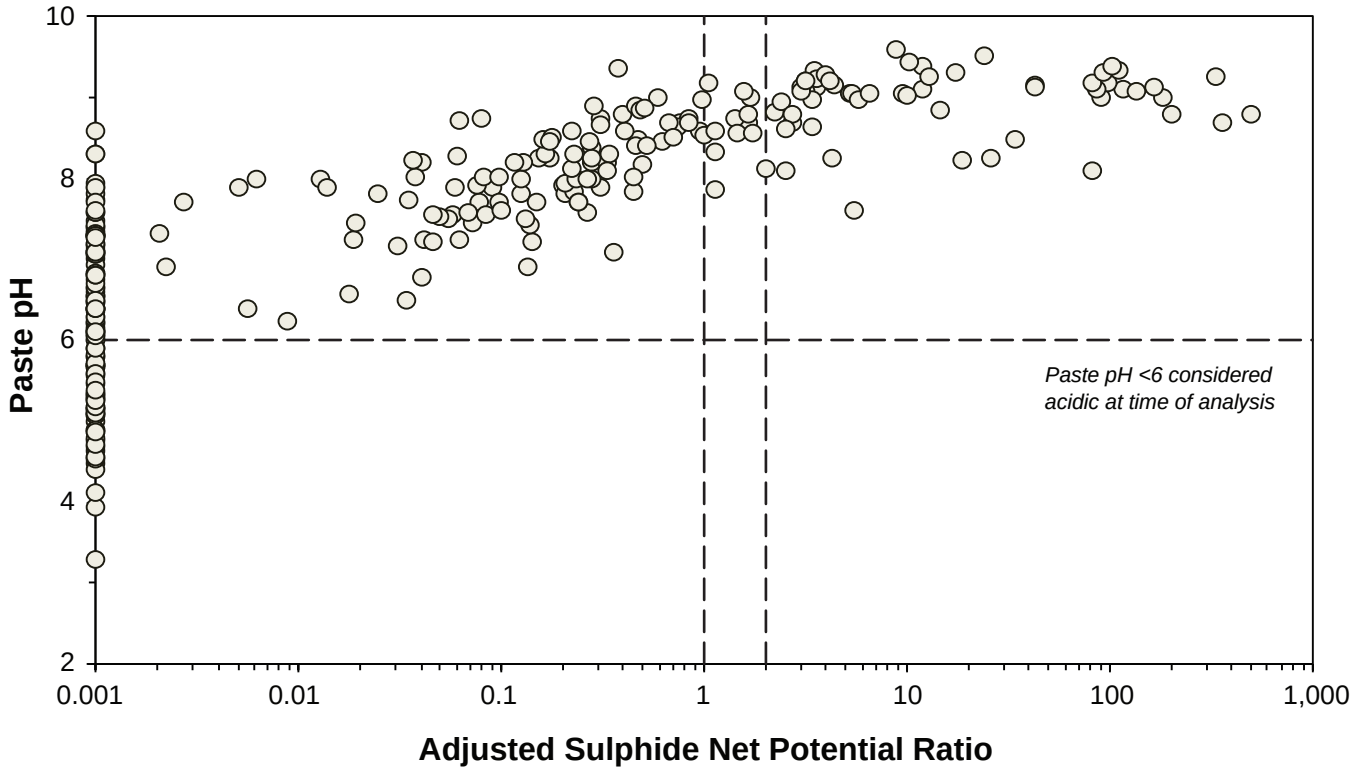

Table 5.1-1 shows the statistical summary of the results for elements with median values exceeding three times the crustal abundance for the Kerr Deposit. The results showed that the elements frequently exceeding three times basalt crustal abundance were: silver, arsenic, barium, bismuth, cadmium, cesium, copper, mercury, potassium, molybdenum, lead, rubidium, sulphur, antimony, selenium, thallium, tungsten, and zinc.

Elements frequently exceeding three times shale crustal abundance were silver, arsenic, barium, cadmium, copper, mercury, molybdenum, lead, sulphur, antimony, selenium, tungsten and zinc.

5.1.1.6 Mineralogy

Mineralogical composition of waste rock samples at the Kerr Deposit was determined by Rietveld XRD and petrographic analysis (transmitted light microscopy).

Appendix 5.1-2 provides the XRD analysis results for the KSM Project. The more common primary minerals identified in four samples from the Kerr Deposit were quartz, muscovite, K-feldspar, clinochlore, and plagioclase. The most common sulphide mineral was pyrite with lesser amounts of chalcopyrite and tennantite ($Cu_{12}As_4S_{13}$). Gypsum was identified as another sulphur-bearing mineral. The most common carbonate minerals were calcite, dolomite, and lesser amounts of siderite.

Appendix 5.1-3 provides the petrographic analysis results for the KSM Project. A description of thin sections of four rock samples at the Kerr Deposit is provided. The most common primary minerals were quartz, quartz+feldspar, sericite, and chlorite. The most common sulphide mineral was pyrite, with fewer observations of chalcocite, chalcopyrite, and trace amounts of bornite and enargite (Cu_3AsS_4). Pyrite ranged from anhedral to subhedral grains, liberated and disseminated in lithic clasts.

5.1.2 Sulphurets Deposit

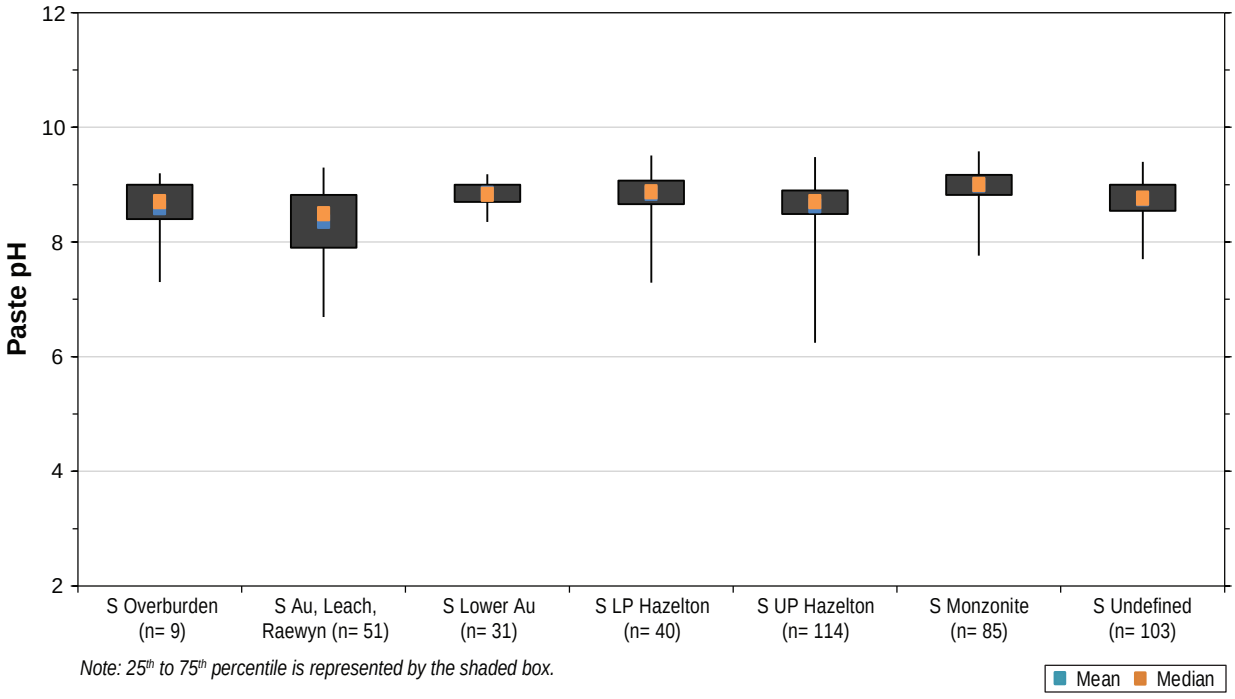
The ABA and solid-phase elemental analyses were conducted on a total of 433 samples from the Sulphurets Deposit (366 drill core samples and 67 pulp samples from drill core samples). Detailed results of the static tests and statistical summaries for the Sulphurets Deposit are presented in Appendix 5.1-1.

5.1.2.1 Paste pH

The results of the paste pH tests on samples from the Sulphurets Deposit by model code are shown in Figure 5.1-14. The paste pH of 433 samples range from a minimum of pH 6.2 (S UP Hazelton) to a maximum of pH 9.6 (S Monzonite), with median values ranging from pH 8.7 (S Au, Leach, Raewyn) to pH 8.8 (S Monzonite).

5.1.2.2 Sulphur Species

A statistical summary of the total-sulphur concentrations for the Sulphurets Deposit is shown in Figure 5.1-15. The total-sulphur concentrations of 433 sample results from the Sulphurets Deposit ranged from a minimum of 0.01% (S Up Hazelton) to a maximum of 7.50% (S Undefined), with median concentrations ranging from 0.36% (S Overburden) to 2.27% (S Lower Au).



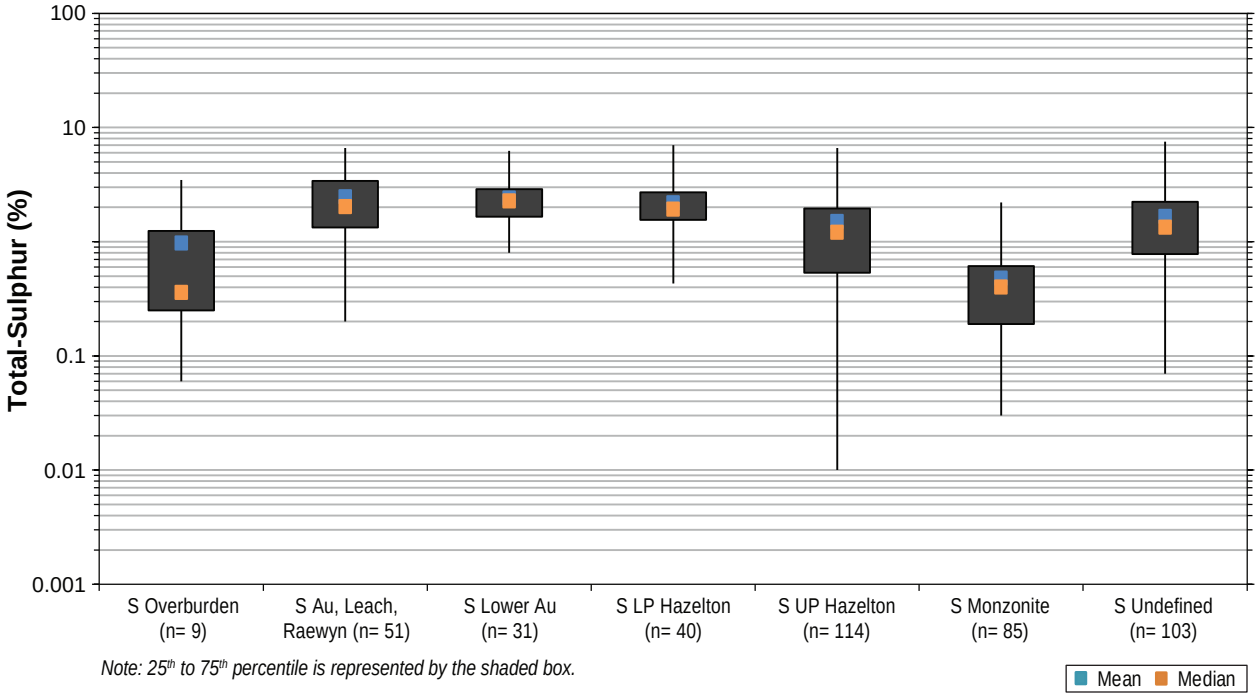
For the Sulphurets Deposit, the total-sulphur concentrations can be categorized into 3 general groups:

- Total-sulphur median concentrations < 1%: S Overburden and S Monzonite;
- Total-sulphur median concentrations between 1 and 2 %: S LP Hazelton, S UP Hazelton, and S Undefined; and
- Total-sulphur median concentrations > 2 %: S Au, Leach, Raewyn and S Lower Au.

A statistical summary of the sulphide-sulphur concentrations for the Sulphurets Deposit is shown in Figure 5.1-16. The sulphide-sulphur content of 369 sample results from the Sulphurets Deposit ranged from a minimum of 0.01% (S Monzonite) to a maximum of 5.82% (S Undefined), with median concentrations ranging from 0.28% (S Overburden) to 2.19% (S Lower Au).

The range of sulphide-sulphur concentrations is similar to the range of total-sulphur concentrations by model code. However sulphide-sulphur concentrations typically are lower than total-sulphur concentrations.

The relationship between sulphide-sulphur and total-sulphur concentrations by model code for the Sulphurets is shown in Figure 5.1-17. In general, there is a strong relationship between sulphide-sulphur and total-sulphur indicating the absence of sulphate-sulphur species such as anhydrite or gypsum. Figure 5.1-18 shows the relationship between acid-soluble sulphate-sulphur and total-sulphur concentrations indicating that there are very low concentrations of sulphate-sulphur in the Sulphurets Deposit samples.



Note: 25th to 75th percentile is represented by the shaded box.

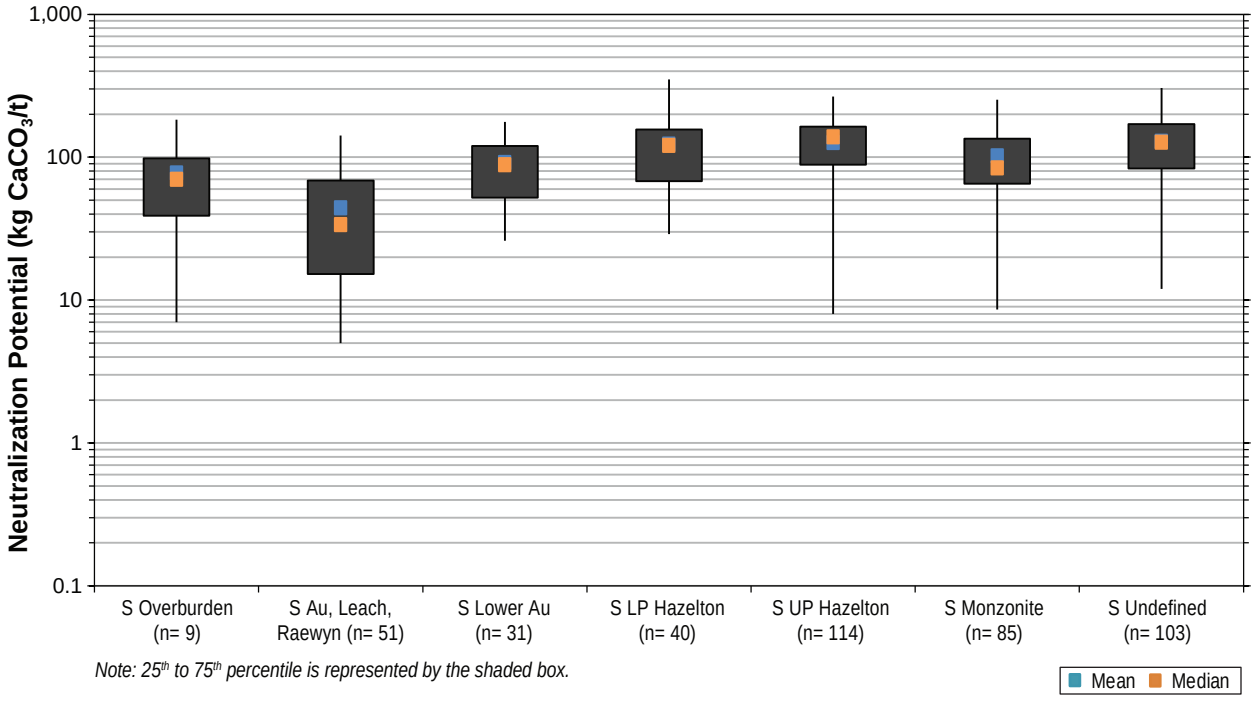
5.1.2.3 Neutralization Potential

A statistical summary of the bulk neutralization potential values for the Sulphurets Deposit is shown in Figure 5.1-19. The Bulk Sobek NP values for 433 samples from the Sulphurets Deposit range from a minimum of 5 kg $CaCO_3$/t (S Au, Leach, Raewyn) to a maximum of 350 kg $CaCO_3$/t (S LP Hazelton), with median values ranging from 34 kg $CaCO_3$/t (S Au, Leach, Raewyn) to 139 kg $CaCO_3$/t (S UP Hazelton).

Bulk Sobek NP values for the Sulphurets Deposit can be grouped into three general categories:



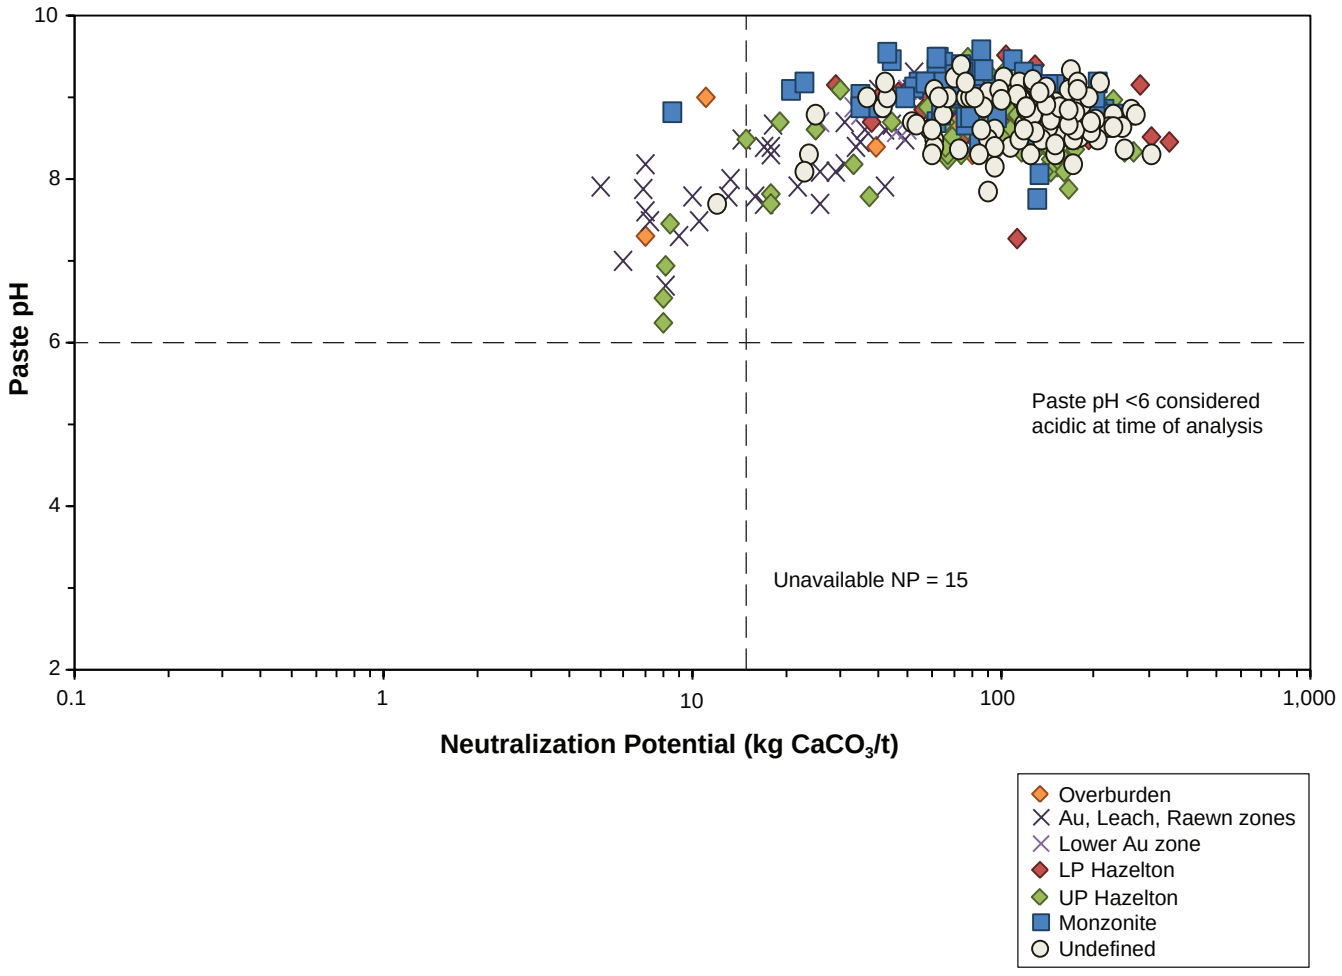
- Median Bulk Sobek NP between 15 kg $CaCO_3$/t and 100 kg $CaCO_3$/t and 25th percentile Bulk Sobek NP lower than 15 kg $CaCO_3$/t l: S Au, Leach, Raewyn;
- Median Bulk Sobek NP between 15 kg $CaCO_3$/t and 100 kg $CaCO_3$/t and 25th percentile Bulk Sobek NP between 15 kg $CaCO_3$/t and 100 kg $CaCO_3$/t: S Overburden, S Lower Au, S Monzonite; and
- Median Bulk Sobek NP greater than 100 kg $CaCO_3$/t: S UP Hazelton, S LP Hazelton and S Undefined.

The relationship between paste pH and Sobek NP values for Sulphurets Deposit samples by model code is presented in Figure 5.1-20. Based on this figure, up to 8 kg $CaCO_3$/t of measured NP could be associated with low paste pH. However, a project unavailable NP value of 15 kg $CaCO_3$/t was previously derived from the complete KSM deposit static test database and the RSFs will be composed of a mix rocks with different model codes from several deposits. Therefore the more conservative earlier estimate of unavailable NP is maintained unchanged. The neutralization potential was adjusted by this estimate of unavailable NP to calculate an adjusted neutralization potential (Adjusted NP).

The correlation between Bulk Sobek NP and Inorg NP is shown in Figure 5.1-21. Below the unavailable NP line, the Inorg NP shows a poor correlation to Sobek NP, suggesting unavailable Sobek NP is comprised of a mixture of carbonate and non-carbonate minerals. Above the unavailable NP line of 15 kg $CaCO_3$/t, the Inorg NP values shows good correlation to Bulk Sobek NP in most of the samples, suggesting that most of the Sobek NP in the Sulphurets Deposit occurs as carbonate minerals. Some samples from UP Hazelton and S Undefined show a poor correlation between Inorg NP and Bulk Sobek NP values. The Inorg NP can be estimated from inorganic carbon analyses as a reasonable surrogate to the Sobek NP for estimation of the available NP in the majority of the Sulphurets Deposit samples.

A plot of a Ca CaNP, assuming that the elemental calcium is present as calcite, versus Bulk Sobek NP is shown in Figure 5.1-22. The Ca CaNP values show a strong correlation with the majority of Sobek NP values, indicating that most of the available Sobek NP in the Sulphurets Deposit occurs as calcium carbonate minerals. Some samples from S Monzonite and UP Hazelton exhibit poor correlation, indicating the presence of a greater proportion of calcium from non-carbonate mineral phases in those samples. Ca CaNP values would be a preferable surrogate to Inorg NP for estimation of the available NP

A plot of a CaMg CaNP, assuming that the elemental calcium and magnesium is present as dolomite, versus Bulk Sobek NP is shown in Figure 5.1-23. The correlation between CaMg CaNP and Sobek NP was poorer than for Ca CaNP, indicating that magnesium occurs predominantly in non-carbonate magnesium-bearing mineral phases. Therefore the CaMg CaNP cannot be used reliably for estimating the available NP in the Sulphurets Deposit.



Note: 25th to 75th percentile is represented by the shaded box.

5.1.2.4 Sulphide Net Potential Ratios

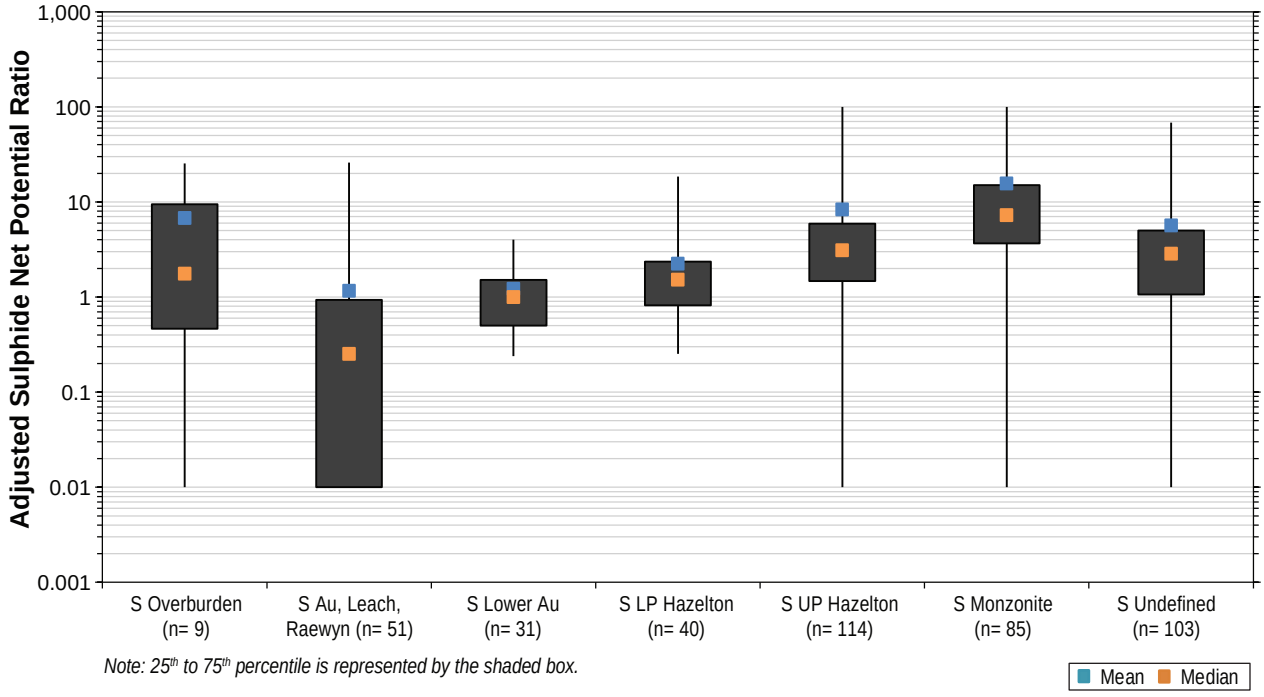
A statistical summary of the adjusted SNPR for the Sulphurets Deposit is shown in Figure 5.1-24. The adjusted SNPR for 433 samples from the Sulphurets Deposit range from a minimum of 0.01 to a maximum of 161, with median values ranging from 0.25 (S Au, Leach, Raewyn) to of 7.24 (S Monzonite). Twenty-five percent of the samples (S Au, Leach, Raewyn and S Lower Au) have median adjusted SNPR<1, indicating that they are potentially acid generating (PAG). Nineteen percent of the samples (S Overburden and S LP Hazelton) have median adjusted SNPR between 1.0 and 2.0, indicating they are possibly acid generating (U). Fifty-six percent of the samples (S UP Hazelton, S Monzonite, and S Undefined) have median adjusted SNPR>2, indicating that they are not potentially acid generating (not-PAG). It is important to note that the 25th percentile of the samples from S UP Hazelton have an SNPR of 1.48, and the 25th percentile of the samples from S Undefined have an SNPR of 1.07, indicating they are potentially acid generating, and possibly acid generating (U), respectively.

The relationship between paste pH and adjusted SNPR of Sulphurets Deposit samples is shown in Figure 5.1-25. Samples with adjusted SNPR of 0.01 were associated with neutral/alkaline pH, indicating that the majority of the samples are in the early stage of acid generation (no acidic samples).

The relationship between sulphide-sulphur and adjusted SNPR of Sulphurets Deposit samples is shown in Figure 5.1-26. It indicates that the samples with a combination of sulphide-sulphur greater than 0.1% and an adjusted SNPR<2 are the most likely to be net ARD generating.

5.1.2.5 Whole Rock and Solid-phase Elemental Analysis

The solid-phase multi-element concentrations in the ML/ARD samples from the Sulphurets Deposit were measured by ICP-MS analysis after strong four-acid digestion and by XRF whole-rock analysis. The results are found in Appendix 5.1-1.



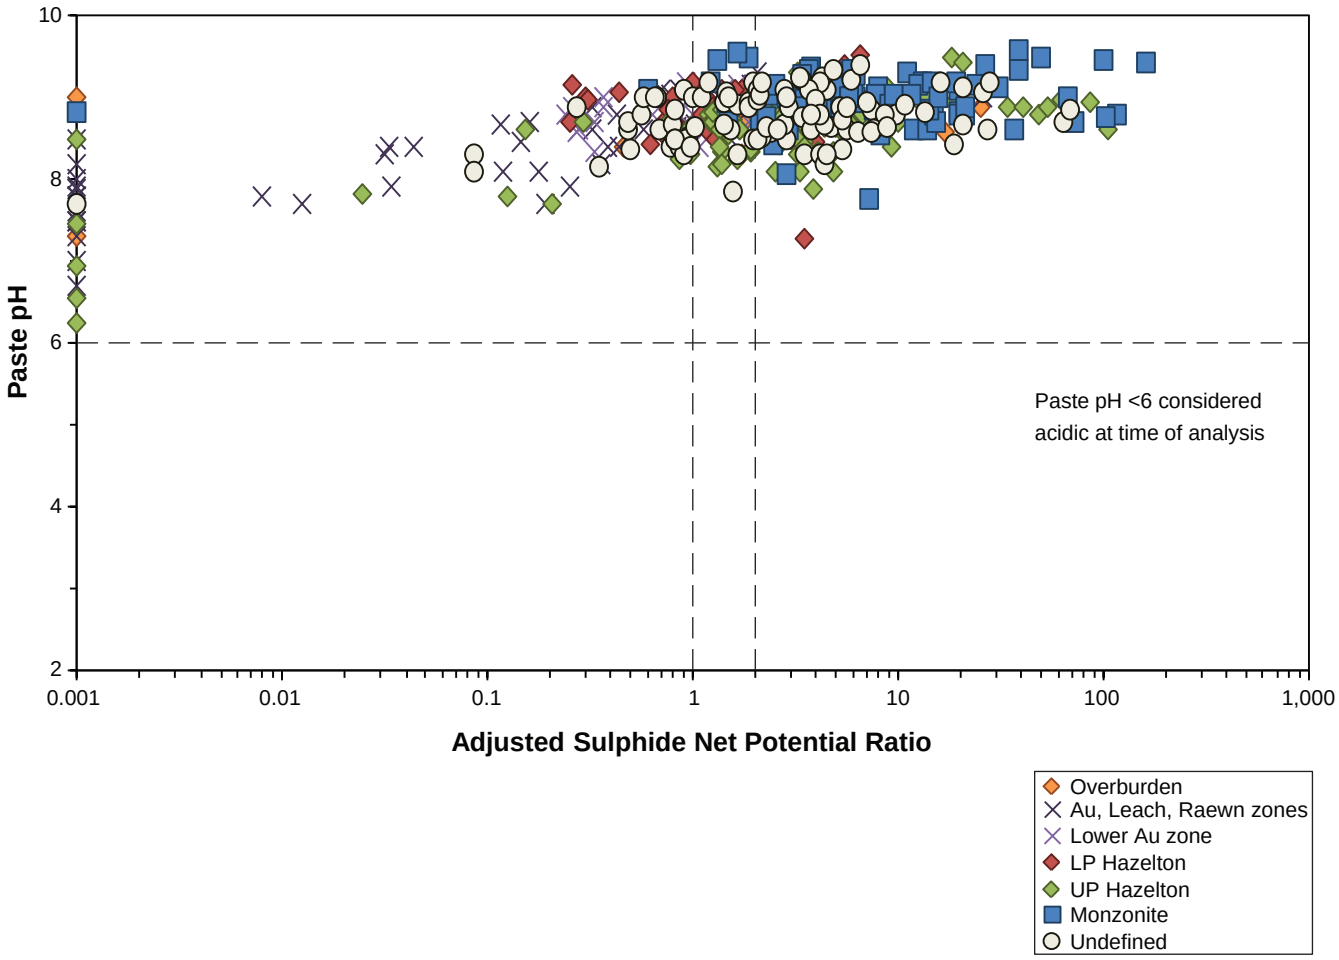
Most of the Sulphurets Deposit rock was comprised of oxide-equivalents of SiO_2 and Al_2O_3. Lesser but still significant amounts of Fe_2O_3, K_2O, CaO, MgO, and Na_2O were present.

The solid-phase concentrations of each element were compared with concentrations found in the earth's crust (crustal abundance) in order to determine which elements occur in anomalously high concentrations (Price 1997). Any elemental concentration higher than three times its crustal abundance was considered an anomalously high concentration.

Table 5.1-2 shows the statistical summary of the results for elements with median concentrations exceeding three times the crustal abundance for the Sulphurets Deposit rocks. The results showed that the elements frequently exceeding three times basalt crustal abundance were: silver, arsenic, barium, bismuth, cadmium, cesium, copper, mercury, potassium, molybdenum, lead, rubidium, sulphur, antimony, selenium, thallium, tungsten, and zinc. Elements frequently exceeding three times shale crustal abundance were: silver, arsenic, barium, cadmium, copper, molybdenum, lead, sulphur, antimony, selenium, tungsten and zinc.

5.1.2.6 Mineralogy

Mineralogical composition of waste rock samples at the Sulphurets Deposit was determined by Rietveld XRD and petrographic analysis (transmitted light microscopy).



Note: 25th to 75th percentile is represented by the shaded box.

Sulphide-Sulphur versus Adjusted Sulphide Net Potential Ratio - Sulphurets Deposit by Model Code

Figure 5.1-26

Rescan™ Engineers & Scientists

Appendix 5.1-2 provides the XRD analysis for the Sulphurets Deposit samples. The more common primary minerals identified in five samples from Sulphurets Deposit were quartz, K-feldspar, muscovite, clinochlore, and plagioclase. The most common sulphide mineral was pyrite with lesser amounts of sphalerite, galena and molybdenite. Other identified sulphur-bearing minerals were gypsum and anhydrite. The most common carbonate minerals were calcite, dolomite, and lesser amount of siderite.

Appendix 5.1-3 provides the petrographic analyses of samples from the Kerr, Sulphurets and Mitchell Deposits. A description of thin sections of five rock samples from the Sulphurets Deposit is provided. The more common primary minerals were quartz+feldspar, sericite, and chlorite. The most common sulphide mineral was pyrite, with lesser observations of chalcopyrite, and trace amounts of molybdenite, bornite, sphalerite, tetrahedrite-tennatite and enargite (Cu_3AsS_4). Pyrite ranged from anhedral to subhedral grains, disseminated in lithic clasts.

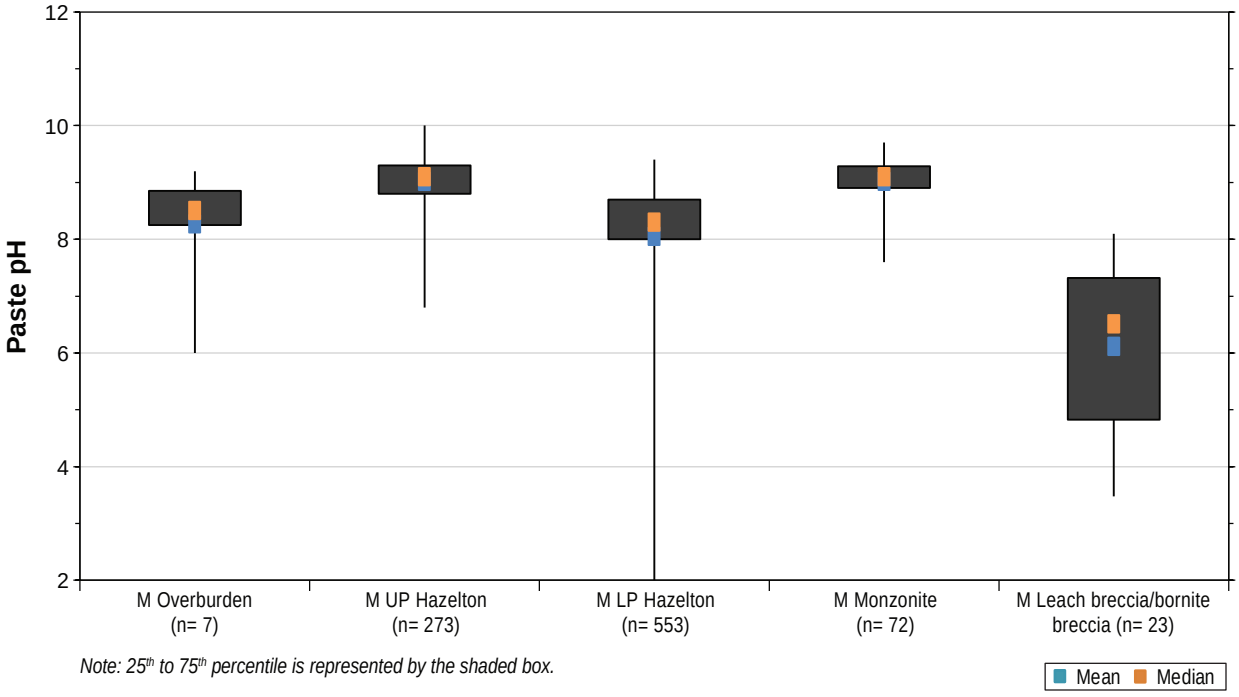
5.1.3 Mitchell Deposit

ABA and solid-phase elemental analyses were conducted on a total of 936 samples from the Mitchell Deposit (809 drill core samples and 127 pulp samples from drill core samples). Details of the static tests and statistical summaries for the Mitchell Deposit are presented in Appendix 5.1-1.

5.1.3.1 Paste pH

The results of the paste pH tests on samples from the Mitchell Deposit by model code are shown in Figure 5.1-27. The paste pH of 936 samples range from a minimum of pH 2.0 (M LP Hazelton) to a maximum of pH 10.0 (M UP Hazelton), with median values ranging from pH 6.5 (M Leach breccia/bornite breccia) to pH 9.1 (M UP Hazelton and M Monzonite).

Static tests of the Mitchell Deposit drill core samples revealed that 5% of the samples had a paste pH less than 6.0, indicating sulphide oxidation and net acid generation had already occurred. Two model codes have minimum paste pH lower than 6.0: M LP Hazelton and M Leach breccia/bornite breccia.



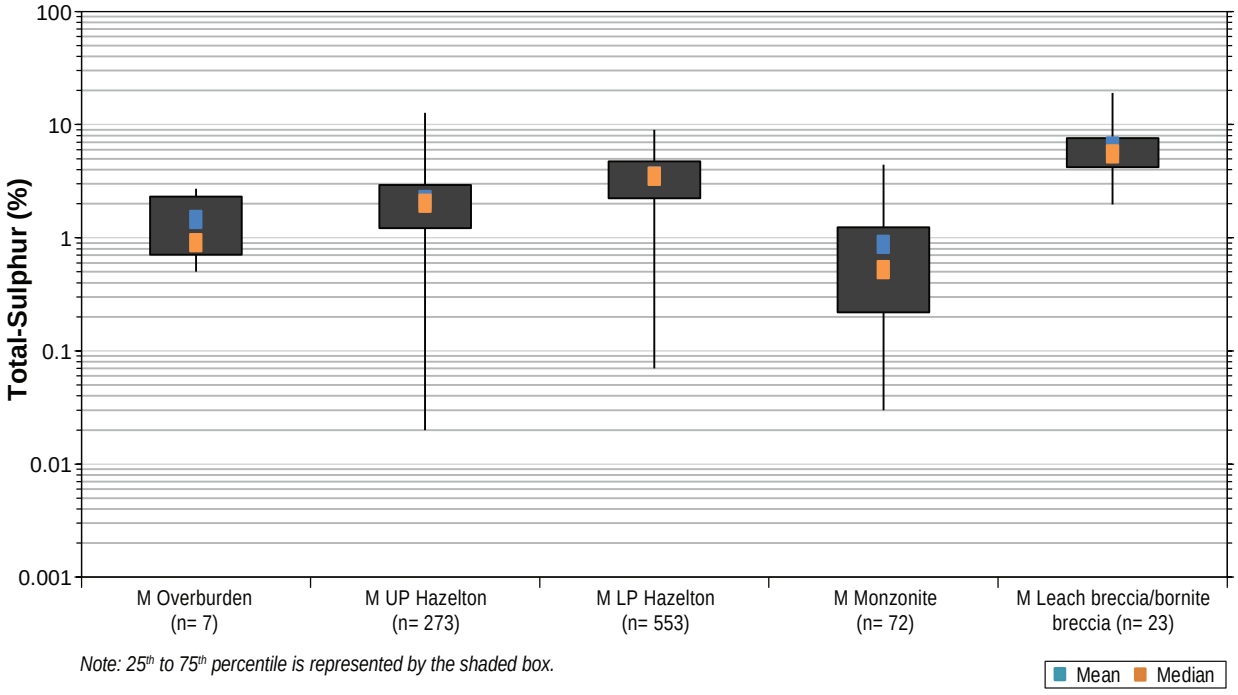
5.1.3.2 Sulphur Species

A statistical summary of the total-sulphur concentrations for the Mitchell Deposit is shown in Figure 5.1-28. The total-sulphur content of all 936 samples from the Mitchell Deposit ranged from a minimum of 0.02% (M UP Hazelton) to a maximum of 19.05% (M Leach breccia/bornite breccia), with median values ranging from 0.52% (M Monzonite) to 5.48% (M Leach breccia/bornite breccia).

For the Mitchell Deposit, the total-sulphur concentrations can be categorized into 3 general groups:

- Total-sulphur median concentrations < 1%: M Overburden and M Monzonite;
- Total-sulphur median concentrations between 1 and 3 %: M UP Hazelton; and
- Total-sulphur median concentrations > 3 %: M LP Hazelton and M Leach breccia/bornite breccia.

A statistical summary of the sulphide-sulphur concentrations for the Mitchell Deposit is shown in Figure 5.1-29. The sulphide-sulphur content of 875 samples from the Mitchell Deposit ranged from a minimum of 0.01% (M Monzonite) to a maximum of 16.35% (M Leach breccia/bornite breccia), with median values ranging from 0.43% (M Monzonite) to 4.04% (M Leach breccia/bornite breccia).



Note: 25th to 75th percentile is represented by the shaded box.

SEABRIDGE GOLD
KSM PROJECT

Statistical Summary of Mitchell Deposit Sulphide-Sulphur Concentrations by Model Code

Figure 5.1-29

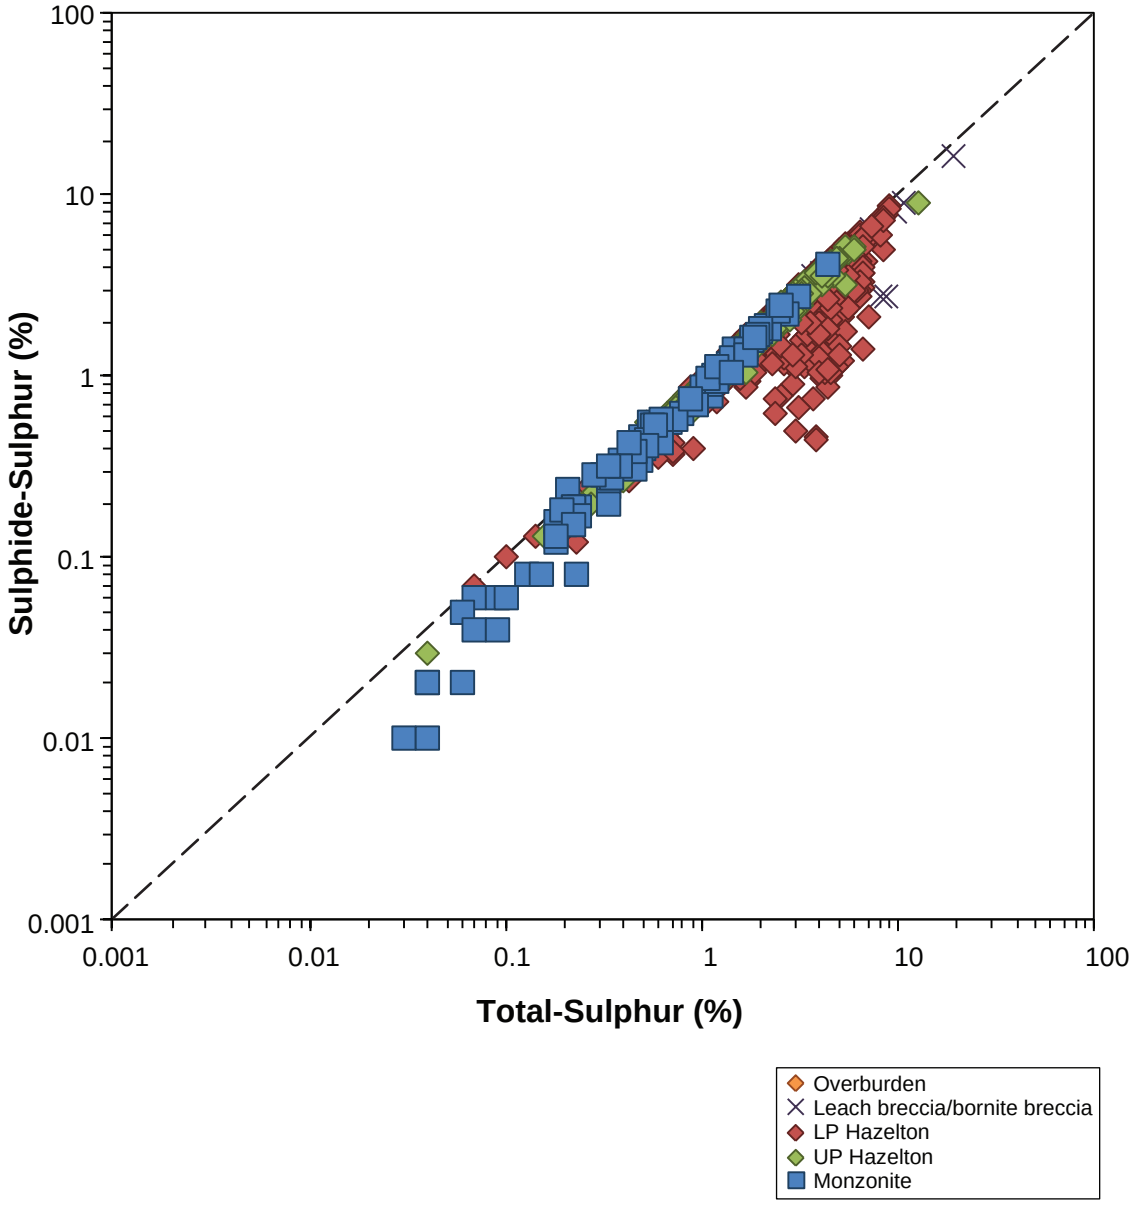
Rescan™ Engineers & Scientists

The relationship between sulphide-sulphur and total-sulphur concentrations by model code for the Mitchell Deposit is shown in Figure 5.1-30. In general, there is a strong relationship between sulphide-sulphur and total-sulphur for total-sulphur concentrations greater than 0.3%. However, the results also clearly show that M LP Hazelton samples show the weakest correlation, with total-sulphur concentrations up to 6.1 times higher than sulphide-sulphur concentrations. Moderately soluble sulphate-sulphur species such as anhydrite and gypsum were detected by XRD analysis in a sample from M LP Hazelton in the Mitchell Deposit.

The relationship between acid-soluble sulphate-sulphur and total-sulphur concentrations by model code for the Mitchell Deposit are shown in Figure 5.1-31. This relationship shows that the acid-soluble sulphate-sulphur component of total-sulphur is variable with high concentrations of acid-soluble sulphate-sulphur in M LP Hazelton samples.

5.1.3.3 Neutralization Potential

A statistical summary of the bulk neutralization potential values for the Mitchell Deposit is shown in Figure 5.1-32. The Bulk Sobek NP values for 936 samples from the Mitchell Deposit range from a minimum of -4 kg $CaCO_3$/t (M Leach breccia/bornite breccia) to a maximum of 342 kg $CaCO_3$/t (M Monzonite), with median values ranging from 8 kg $CaCO_3$/t (M Leach breccia/bornite breccia) to 63 kg CaCO3/t (M Monzonite).



Bulk Sobek NP values for the Mitchell Deposit can be grouped into two general categories:

- Median Bulk Sobek NP lower than 15 kg $CaCO_3$/t: M Leach breccia/bornite breccia
- Median Bulk Sobek NP between 15 kg $CaCO_3$/t and 100 kg $CaCO_3$/t: M Overburden, M UP Hazelton, M LP Hazelton, and M Monzonite.

The relationship between paste pH and Bulk Sobek NP values for Mitchell Deposit samples by model codes are presented in Figure 5.1-33. Based on this figure, up to 15 kg $CaCO_3$/t of measured NP could be associated with acidic paste pH. The neutralization potential was adjusted by this estimate of 15 kg $CaCO_3$/t (unavailable NP) to calculate an adjusted neutralization potential (Adjusted NP).

The correlation between Bulk Sobek NP and Inorg NP is shown in Figure 5.1-34. Below the unavailable NP line, the Inorg NP shows a poor correlation to Sobek NP, predominantly in M LP Hazelton and M Leach breccia/bornite breccia, suggesting unavailable Sobek NP is comprised of a mixture of carbonate and non-carbonate minerals. Above the unavailable NP line of 15 kg $CaCO_3$/t, the Inorg NP shows a stronger correlation to Bulk Sobek NP, predominantly in M Monzonite, suggesting that most of the available Sobek NP in M Monzonite occurs as carbonate minerals. Some samples from M UP Hazelton and M LP Hazelton show a poor correlation between Inorg NP and Bulk Sobek NP, suggesting Sobek NP is comprised of a mixture of carbonate and non-carbonate minerals.

A plot of a Ca CaNP, assuming that the elemental calcium is present as calcite, versus Bulk Sobek NP is shown in Figure 5.1-35. The Ca CaNP values show a strong correlation with the majority of Sobek NP values, indicating that most of the available Sobek NP in the Mitchell Deposit occurs as calcium carbonate minerals. Some samples M LP Hazelton exhibit a poor correlation, indicating the presence of a greater proportion of calcium from non-carbonate mineral phases. Ca CaNP values would be a preferable surrogate to Inorg NP for estimation of the available NP.

Calcium Neutralization Potential versus Bulk Sobek Neutralization Potential in the Mitchell Deposit by Model Code

Figure 5.1-35

Rescan™ Engineers & Scientists

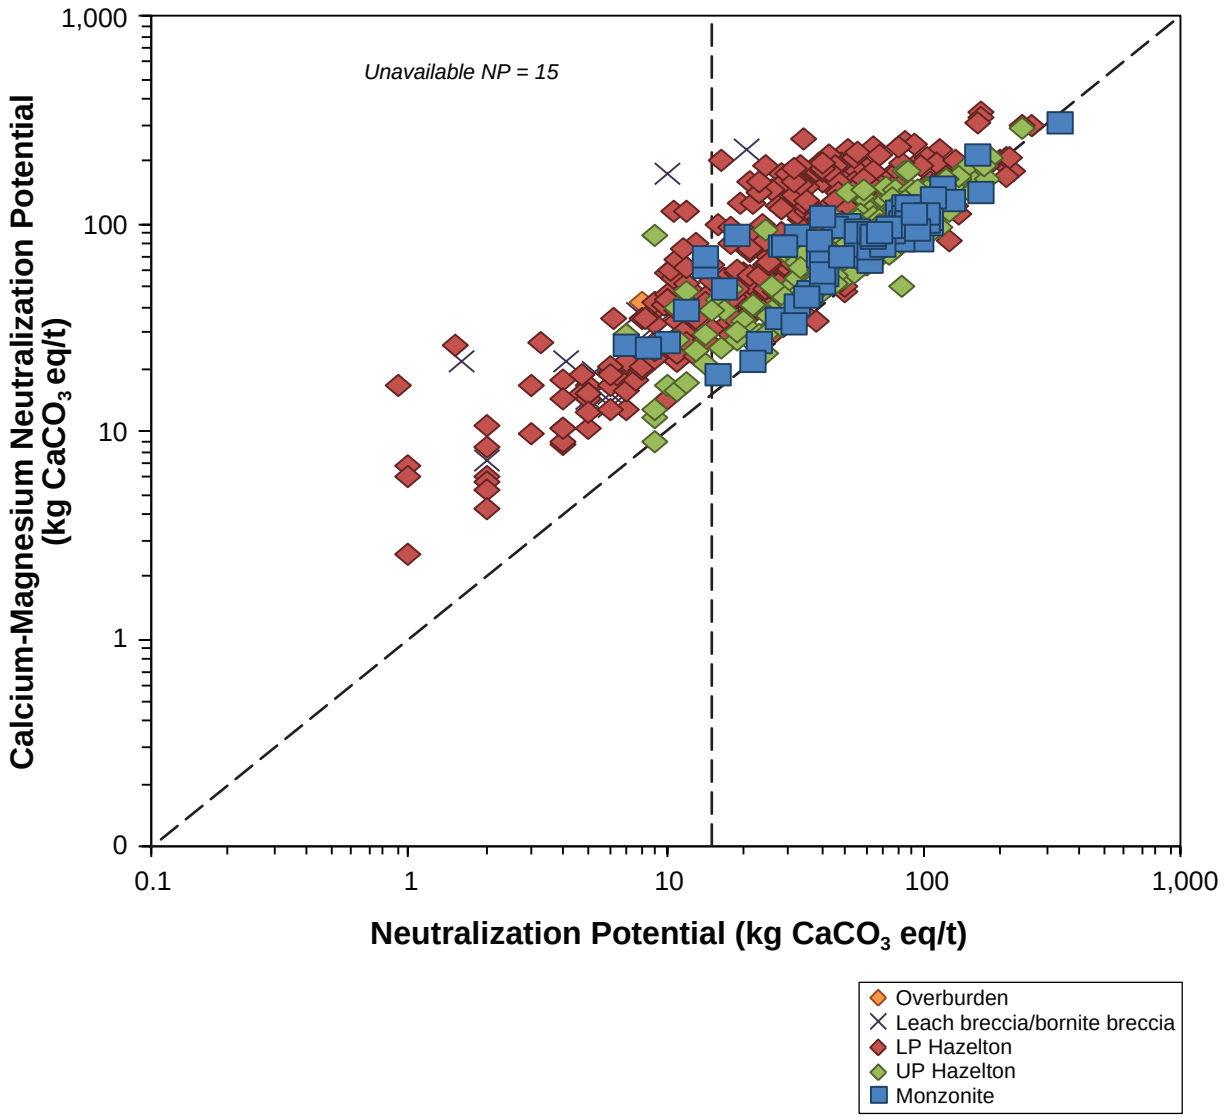
A plot of a CaMg CaNP, assuming that the elemental calcium and magnesium is present as dolomite, versus Bulk Sobek NP is shown in Figure 5.1-36. The correlation between CaMg CaNP and Sobek NP was poorer than for Ca CaNP, indicating that a measurable portion of CaMg CaNP is not providing neutralization or is unreactive. This poor correlation indicates that magnesium occurs predominantly in non-carbonate magnesium-bearing mineral phases. Therefore the CaMg CaNP cannot be used reliably for estimating the available NP in the Mitchell Deposit.

5.1.3.4 Sulphide Net Potential Ratios

A statistical summary of the adjusted SNPR for the Mitchell Deposit is shown in Figure 5.1-37. The adjusted SNPR for 936 samples from the Mitchell Deposit range from a minimum of 0.01 to a maximum of 246, with median values ranging from 0.01 (M Leach breccia/bornite breccia) to 3.4 (M Monzonite) . Seventy-four percent of the samples have adjusted SNPR<1, indicating that they are potentially acid generating (PAG). From those samples 138 (20%) were assigned a default SNPR of 0.01, indicating that the samples had NP values equal or lower than 15 kg$CaCO_3$/t, suggesting that the onset of acidic conditions would be rapid in these samples. Twelve percent of the samples have an adjusted SNPR between 1.0 and 2.0, indicating they are possibly acid generating (UPAG) and 14 % of the samples have adjusted SNPR>2, indicating that they are not potentially acid generating (not-PAG).

The relationship between paste pH and adjusted SNPR of Mitchell Deposit samples is shown in Figure 5.1-38. Samples with an adjusted SNPR of 0.01 were associated with both acidic and neutral/alkaline pH, indicating that samples from M LP Hazelton and M Leach breccia/bornite breccia are in in an advanced stage of acid generation (acidic samples) while samples from M Overburden, M UP Hazelton, and M Monzonite are in the early stage of acid generation (no acidic samples).

The relationship between sulphide-sulphur and adjusted SNPR of Mitchell Deposit samples located below MTF and above MTF is shown in Figure 5.1-39. The samples with a combination of sulphide-sulphur greater than 0.1% and adjusted SNPR<2 are the most likely to be net ARD generating in the long term.



5.1.3.5 Whole Rock and Solid-phase Elemental Analysis

The multi-element concentrations in the ML/ARD samples from the Mitchell Deposit were measured by ICP-MS analysis after strong four-acid digestion and by XRF whole-rock analysis. The results are found in Appendix 5.1-1.

Most of the Mitchell Deposit rock was comprised of oxide-equivalents of SiO_2 and Al_2O_3. Lesser but still significant amounts of Fe_2O_3, K_2O, CaO, MgO, and Na_2O were detected.

The solid-phase concentrations of each element were compared with concentrations found in the earth's crust (crustal abundance) in order to determine which elements occur in anomalously high concentrations (Price 1997). Any elemental concentration higher than three times its crustal abundance was considered an anomalously high concentration.

Table 5.1-3 shows the statistical summary of the results for elements with median concentrations exceeding three times the crustal abundance for the Mitchell Deposit. The results showed that the elements frequently exceeding three times basalt crustal abundance were silver, arsenic, barium, bismuth, cadmium, cesium, copper, potassium, molybdenum, lead, rubidium, sulphur, antimony, selenium, thallium, vanadium and tungsten. Elements frequently exceeding three times shale crustal abundance were silver, arsenic, barium, cadmium, chromium, copper,, molybdenum, lead, sulphur, antimony, selenium, vanadium, and tungsten.

Sulphide-Sulphur versus Adjusted Sulphide Net Potential Ratio in the Mitchell Deposit by Model Code

Figure 5.1-39

Rescan™ Engineers & Scientists

5.1.3.6 Mineralogy

Appendix 5.1-2 provides the results of XRD analyses for samples at the Mitchell Deposit. The most common primary minerals identified in 17 samples from Mitchell Deposit were quartz, muscovite, plagioclase, K-feldspar, clinochlore, and biotite. The most common sulphide mineral was pyrite with lesser amounts of molybdenite. Anhydrite and gypsum were identified in one sample. The most common carbonate minerals were calcite, dolomite, and lesser amount of siderite.

Appendix 5.1-3 provides the petrographic analyses of rock samples from the Kerr, Sulphurets and Mitchell Deposit. A description of thin sections of 17 rock samples from the Mitchell Deposit is provided. The most common primary minerals were quartz, quartz+feldspar, quartz+plagioclase, sericite, chlorite, illite, and biotite. The most common sulphide mineral was pyrite, with lesser observations of chalcopyrite, and trace amounts of chalcocite, enargite (Cu_3AsS_4), molybdenite, tetrahedrite-tennantite, and sphalerite. Pyrite ranged from anhedral to subhedral grains, liberated and disseminated in lithic clasts.

5.1.4 Iron Cap Deposit

ABA and solid-phase elemental analysis were conducted on a total of 356 samples from the Iron Cap deposit (224 drill core samples and 132 pulp samples from drill core samples). Detailed results of the static tests and statistical summaries for the Iron Cap deposit are presented in Appendix 5.1-1.

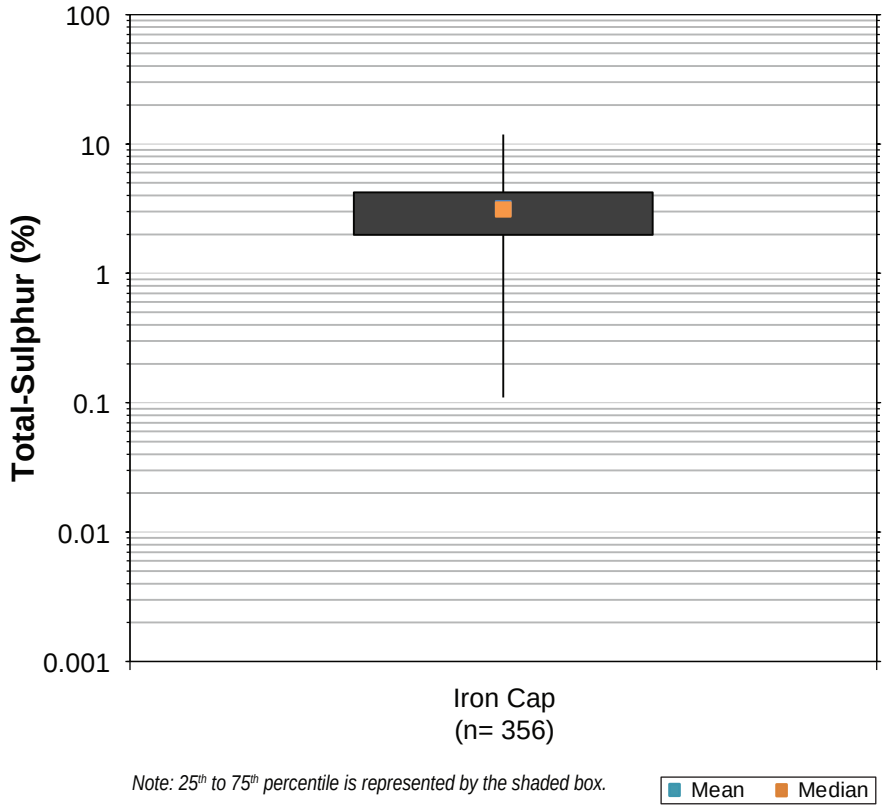
5.1.4.1 Paste pH

The results of the paste pH tests of samples from the Iron Cap deposit are shown in Figure 5.1-40. The paste pH of 356 samples results ranged from a minimum of 3.0 to a maximum of 9.6, with a mean of 7.9 and a median of 8.3.

Static tests of the Iron Cap deposit drill core samples revealed that 8 percent of the samples had a paste pH less than 6.0 at the time of laboratory testing, indicating sulphide oxidation and net acid generation had already occurred.

5.1.4.2 Sulphur Species

The results of the total-sulphur analyses of the Iron Cap deposit samples are shown in Figure 5.1-41. The total-sulphur content of 356 samples ranged from a minimum of 0.11% to a maximum of 11.86%, with a mean of 3.17% and a median of 3.11%.



Sulphide-sulphur analyses for Iron Cap deposit samples are shown in Figure 5.1-42. Sulphide-sulphur concentrations ranged from a minimum of 0.12 % to a maximum of 8.60%, with a mean of 2.52% and a median of 2.45%.

The relationship between sulphide-sulphur and total-sulphur concentrations for the Iron Cap deposit samples is shown in Figure 5.1-43. In general, there is a strong relationship between sulphide-sulphur and total-sulphur indicating the sulphur species is mostly comprised of sulphide-sulphur.

The relationship between acid-soluble sulphate-sulphur and total-sulphur concentrations for the Iron Cap deposit samples is shown in Figure 5.1-44. This relationship shows that there is no correlation between acid-soluble sulphate-sulphur and total-sulphur, indicating there is minor sulphate sulphur present.

5.1.4.3 Neutralization Potential

Neutralization Potential of Iron Cap deposit samples is shown in Figure 5.1-45. Neutralization Potential values of 356 samples ranged from a minimum of -5 kg $CaCO_3$/t to a maximum of 258 kg $CaCO_3$/t with a mean value of 38 kg $CaCO_3$/t and a median value of 31 kg $CaCO_3$/t.

Statistical Summary of Iron Cap Deposit Bulk Sobek Neutralization Potential Values

Figure 5.1-45

Rescan™ Engineers & Scientists

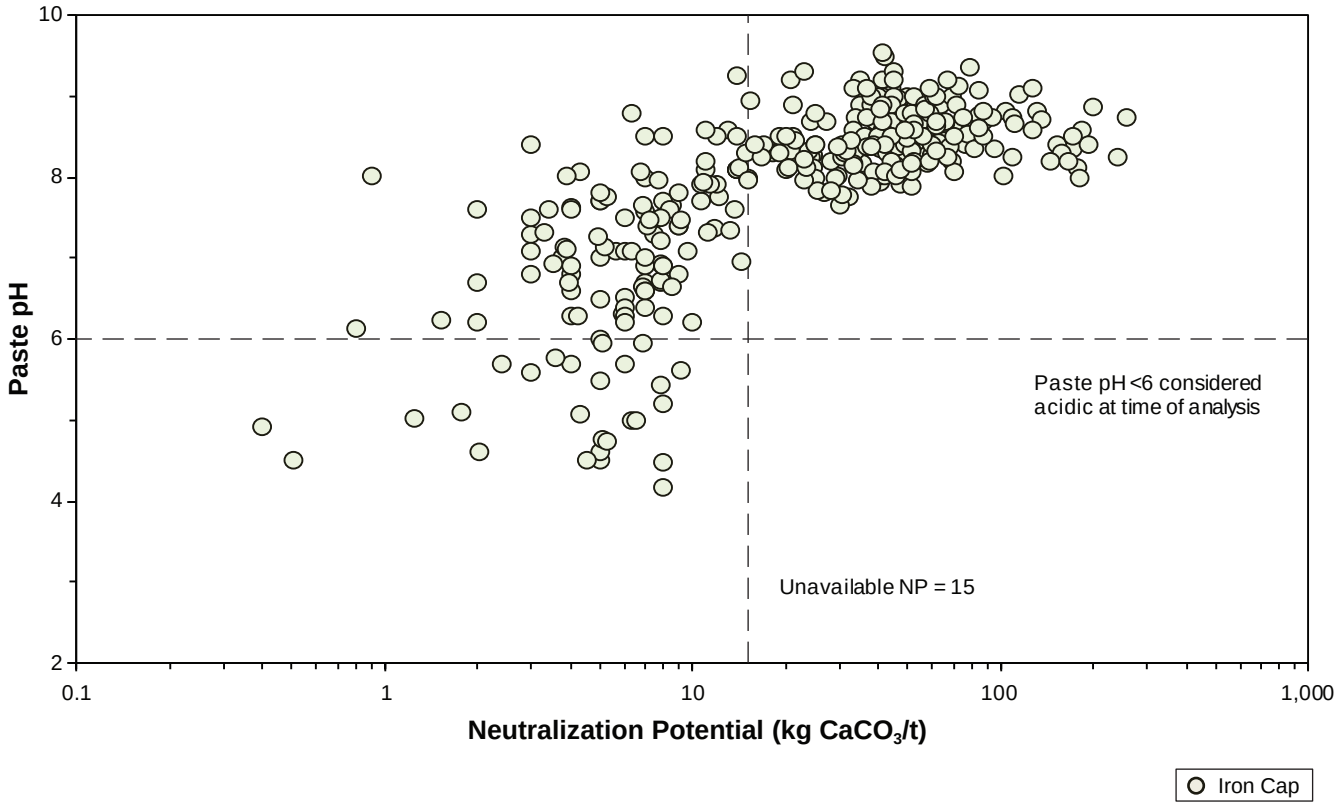
The relationship between paste pH and Sobek NP values for Iron Cap Deposit samples is presented in Figure 5.1-46. Based on this figure, up to 15 kg $CaCO_3$/t of measured NP could be associated with with acidic paste pH values. The neutralization potential was adjusted by this estimate of 15 kg $CaCO_3$/t (unavailable NP) to calculate an adjusted neutralization potential (Adjusted NP).

The correlation between Bulk Sobek NP and Inorg NP is shown in Figure 5.1-47. Below the unavailable NP line, the Inorg NP shows a poor correlation to Sobek NP, suggesting unavailable Sobek NP is comprised of a mixture of carbonate and non-carbonate minerals. Above the unavailable NP line of 15 kg $CaCO_3$/t, the Inorg NP shows a stronger correlation to Bulk Sobek NP, suggesting that most of the Sobek NP in the Iron Cap deposit samples occurs as carbonate minerals. Therefore the Inorg NP can be estimated from inorganic carbon analyses as a reasonable surrogate to the Sobek NP for estimation of the available NP.

A plot of a Calcium CaNP (Ca CaNP), assuming that the elemental calcium is present as calcite, versus Bulk Sobek NP is shown in Figure 5.1-48. The Ca CaNP values show a strong correlation with the majority of Sobek NP values, indicating that most of the available Sobek NP in the Iron Cap deposit occurs as calcium carbonate minerals. Some samples with values below the unavailable NP exhibit poor correlation, indicating the presence of a greater proportion of calcium from non-carbonate mineral phases.

A plot of a Calcium-Magnesium CaNP (CaMg CaNP), assuming that the elemental calcium and magnesium is present as dolomite, versus Bulk Sobek NP is shown in Figure 5.1-49. Below the unavailable NP line, the CaMg CaNP shows a poor correlation to Sobek NP, indicating that magnesium occurs predominantly in non-carbonate magnesium-bearing mineral phases. Above the unavailable NP line, the CaMg CaNP shows a stronger correlation to Bulk Sobek NP, suggesting that there is occurrence of calcium and magnesium carbonate minerals.

5.1.4.4 Sulphide Net Potential Ratios



The adjusted SNPR for 356 Iron Cap deposit samples are shown in Figure 5.1-50. They range from a minimum of 0.01 to a maximum of 41.6, with a mean of 0.98 and a median of 0.14. Eighty-seven percent of the samples have adjusted SNPR<1, indicating that they are potentially acid generating (PAG). One hundred and thirty-seven samples (39%) were assigned an adjusted SNPR of 0.01, indicating that the samples had NP values equal or lower than 15 kg$CaCO_3$/t, meaning the onset of acidic conditions is expected to be rapid in these. Five percent of the samples have an adjusted SNPR between 1.0 and 2.0, indicating they are possibly acid generating (UPAG) and 8 % of the samples have adjusted SNPR>2, indicating that they are not potentially acid generating (not-PAG).

The relationship between paste pH and adjusted SNPR of Iron Cap deposit samples is shown in Figure 5.1-51. Samples with adjusted SNPR of 0.01 were associated with both acidic and neutral/alkaline pH, indicating that some samples are in an advanced stage of acid generation (acidic samples) and some samples are in the early stage of acid generation (no acidic samples).

The relationship between sulphide-sulphur and adjusted SNPR for Iron Cap deposit samples is shown in Figure 5.1-52. It indicates that the samples with a combination of sulphide-sulphur greater than 0.1% and an adjusted SNPR<2 are the most likely to be net ARD generating.

5.1.4.5 Solid-phase Elemental Analysis

The multi-element concentrations in the ML/ARD samples from the Iron Cap deposit were measured by ICP-MS analysis after strong four-acid digestion. The results can be found in Appendix 5.1-1.

Table 5.1-4 shows the statistical summary of the results for elements with median concentrations exceeding three times the crustal abundance for the Iron Cap deposit. The results showed that the elements frequently exceeding three times basalt crustal abundance were: silver, arsenic, bismuth, cadmium, cesium, copper, potassium, molybdenum, lead, antimony, rubidium, sulphur, selenium, tungsten, and zinc. Elements frequently exceeding three times shale crustal abundance were: silver, arsenic, cadmium, copper, molybdenum, lead, sulphur, antimony, selenium, tungsten, and zinc.

5.1.4.6 Mineralogy

Mineralogical composition of waste rock samples at Iron Cap Deposit was determined by Rietveld XRD and petrographic analysis (transmitted light microscopy).

Appendix 5.1-2 provides the XRD analysis results for samples from the Iron Cap deposit. The more common primary minerals identified in six samples from the Iron Cap deposit were quartz, K-feldspar, muscovite, and plagioclase. The most common sulphide mineral was pyrite. The most common carbonate minerals were calcite and lesser amounts of dolomite and siderite.

5.2 KINETIC TESTS

5.2.1 Humidity Cells

Forty laboratory humidity cells were initiated and operated to assess the ML/ARD properties of potential waste rock and pit wall rock from the Kerr, Mitchell, Sulphurets, and Iron Cap deposits. This section of the report incorporates results collected up till the end of July 2012.

For the purpose of this discussion, the humidity cells have been divided by deposit and the position relative to Mitchell Thrust Fault (MTF) for the Mitchell Deposit (e.g. upper and lower panels), and are further discussed with reference to the model code from the Seabridge ABA block model (M. Lechner, pers. comm.). Not all model codes are represented by humidity cells. S Au, Leach, Raewyn, S LP Hazelton, S Monzonite and M Overburden are not represented. The following percentage of waste rock is represented by humidity cells: Kerr 98.7% (SNPR<2) and 1.3% (SNPR >2); Sulphurets 21.6% (SNPR<2) and 14% (SNPR >2); Mitchell 75.2 % (SNPR<2) and 19.1% (SNPR >2); and Iron Cap 100% (Table 4.4-3).

5.2.1.1 Pre-test Static Test Results

Subsamples of humidity cell material were obtained to determine pre-humidity cell solid-phase static test properties and analyses included ABA, solid-phase elemental concentration analysis, and mineralogy.

The results of the pre-humidity cell solid-phase static tests for the Project are found in Appendix 5.2-1.

Detailed analytical mineralogy and petrographic studies for waste rock can be found in Appendices 5.1-2 and 5.1-3, respectively.

Paste pH

Figure 5.2-1 presents the paste pH of the humidity cells samples in relation to the statistical distribution of the paste pH determined for all waste rock samples by block model code. The results show that the majority of the humidity cells samples are within the pH interquartile range for their model code. Some humidity cell samples exhibited pH variability towards the lower range of all waste rock samples (Kerr, S Overburden, M UP Hazelton, M LP Hazelton, and Iron Cap).

Sulphur Species

Figure 5.2-2 presents total-sulphur concentrations of the humidity cells samples in relation to the statistical distribution of total-sulphur concentrations determined for all waste rock samples by model code. The results show that the majority of the humidity cells samples are within the total-sulphur interquartile range for their model code. Some humidity cell samples exhibited total-sulphur concentrations variability towards the lower range of all waste rock samples (M UP Hazelton, M Monzonite, and Iron Cap) and some humidity cell samples exhibited total-sulphur concentrations variability towards the higher range of all waste rock samples (Kerr, S Overburden, M UP Hazelton and M Leach breccia/bornite breccia).

Figure 5.2-3 presents sulphide-sulphur concentrations of the humidity cells samples in relation to the statistical distribution of sulphide-sulphur concentrations determined for all waste rock samples by model code. The results show that the majority of the humidity cells samples are within the sulphide-sulphur interquartile range for their model code. Some humidity cell samples exhibited sulphide-sulphur concentrations variability towards the lower range of all waste rock samples (M UP Hazelton, M Monzonite and Iron Cap) and some humidity cell samples exhibited total-sulphur concentrations variability towards the higher range of all waste rock samples (Kerr, S Overburden, M UP Hazelton and M Leach breccia/bornite breccia).

Neutralization Potential

Figure 5.2.4 presents the NP values of the humidity cell samples in relation to the statistical distribution of NP values determined for all waste rock samples by model code. The results show that the majority of the humidity cells samples are within the NP interquartile range for their model code. Some humidity cell samples exhibited NP variability towards the lower range of all waste rock samples (S Overburden, M UP Hazelton, M LP Hazelton, and M Monzonite).

Adjusted Sulphide Net Potential Ratio

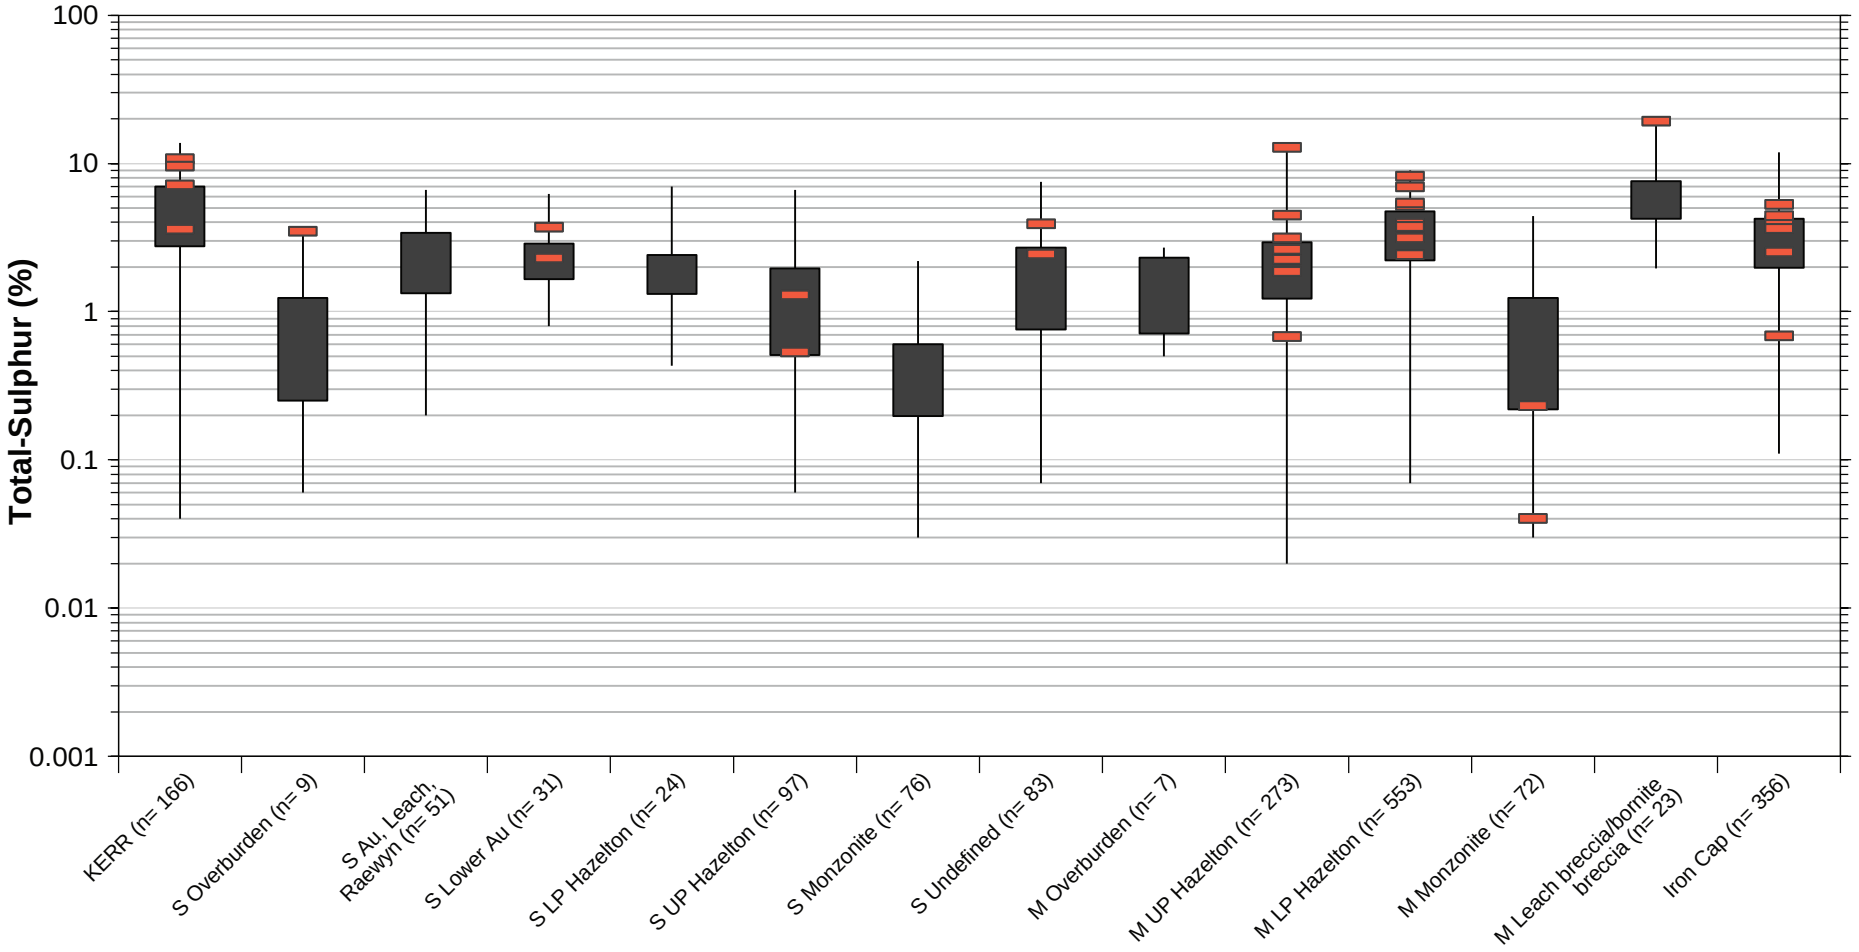

Figure 5.2.5 presents the adjusted SNPR of the humidity cell samples in relation to the statistical distribution of adjusted SNPR determined for all waste rock samples by model code. The results show that the majority of the humidity cells samples are within the adjusted SNPR interquartile range for their model code. Some humidity cell samples exhibited adjusted SNPR variability towards the lower range of all waste rock samples (S Overburden, S Undefined, M UP Hazelton, and M LP Hazelton).

Whole Rock and Solid-phase Elemental Analysis

The multi-element concentrations in humidity cell samples from the Kerr, Sulphurets and Mitchell Deposits were measured by ICP-MS analysis after strong four-acid digestion and by XRF whole-rock analysis. The results are found in Appendix 5.2-1.

Most of the humidity cell samples were comprised of oxide-equivalents of SiO_2 and Al_2O_3, which is consistent with the dominant presence of quartz, feldspar minerals, and other aluminosilicate minerals in KSM rocks. Also consistent with the general mineralogy, there were lesser but still significant amounts of Fe_2O_3, K_2O, CaO, MgO, and Na_2O.

The solid-phase concentrations of each element were compared with concentrations found in the earth's crust (crustal abundance) in order to determine which elements occur in anomalously high concentrations (Price 1997). Any elemental concentration higher than three times its crustal abundance was considered an anomalously high concentration.

Note: 25th to 75th percentile is represented by the shaded box. The red bars indicate individual humidity cells.

Table 5.2-1 shows the statistical summary of the results for elements concentrations exceeding three times the crustal abundance. The results showed that the elements frequently exceeding three times basalt crustal abundance were silver, arsenic, bismuth, cesium, copper, potassium, molybdenum, lead, rubidium, sulphur, antimony, selenium, thallium and tungsten. Elements frequently exceeding three times shale crustal abundance were silver, copper, molybdenum, sulphur, and selenium.

Mineralogy

Detailed analytical mineralogy and petrographic studies for waste rock can be found in Appendix 5.1-2 and 5.1-3, respectively, and are referred to elsewhere in report Section 5.1.

5.2.1.2 Kinetic Test Results

The following discussion presents the results of leachate analyses from the humidity cells for each deposit for:

- Indicators of acid generation (pH, sulphate, acidity, and alkalinity);
- Elements that contribute to acidity (aluminum, iron, and manganese);
- Barium which is most commonly associated with barite ($BaSO_4$), a highly insoluble mineral;
- Trace elements with elevated concentrations in the last 10 weekly cycles relative to water quality guidelines. Identification of these elements can be used to inform treatment design decisions, including treatment at the proposed Water Treatment Plant (WTP), and water quality modelling; and
- Calcium and magnesium which commonly occur in carbonate mineral phases and are associated with the neutralization potential.

Kerr Deposit

Four humidity cells of the model code KERR have operated for either 61 or 129 weeks at the time of this report. The complete dataset for humidity cell leachate concentrations for the Kerr Deposit are presented in Appendix 5.2-2. The leach rates for additional parameters are presented in Appendix 5.2-3.

pH, Sulphate, Acidity, and Alkalinity

Two Kerr humidity cells were near-neutral (HC20 and 22) and two Kerr humidity cells were acidic (HC21 and 23). The pH of the near-neutral humidity cells remained near-neutral after 129 weeks; however, HC22 became acidic with pH values of 5.5 to 6.5 between weeks 20 and 79, and with pH values of 6.5 to 5.9 between weeks 79 and 129. The pH of the two acidic humidity cells decreased for the first 16 weeks. The pH of HC 21 was stable between weeks 16 and 61, while the pH for HC23 was stable between weeks 16 and 51, but decreased between weeks 51 and 61 (Figure 5.2-6).

Initial decreases in sulphate production rates in the near-neutral humidity cells represented the flushing of surface sulphate precipitates. The stable sulphate production rates and stable pH values in the near-neutral humidity cells indicated that any acid produced by sulphide oxidation was effectively neutralized. Sulphate production rates in HC23 decreased to week 51 and subsequently rapidly increased for the last 9 weeks. Steady-state conditions were not reached, and increased sulphate production coincident with decreases in pH indicated increased sulphide oxidation rates (Figure 5.2-6).

Weekly pH and Sulphate Production Rates, Kerr Deposit Waste Rock Humidity Cells

Figure 5.2-6

Rescan™ Engineers & Scientists

Alkalinity was not detected in the acidic humidity cells. Acidity and alkalinity trends for the near-neutral humidity cells followed the pH trends closely and were generally stable for 129 weeks. Similarly, acidity closely matched the pH trends in the acidic humidity cells with increased acidity production in the first 16 weeks, followed by stable rates between weeks 16 and 51, and increased acidity production at week 51 in HC23 (Figure 5.2-7).

Elements that Contribute to Acidity

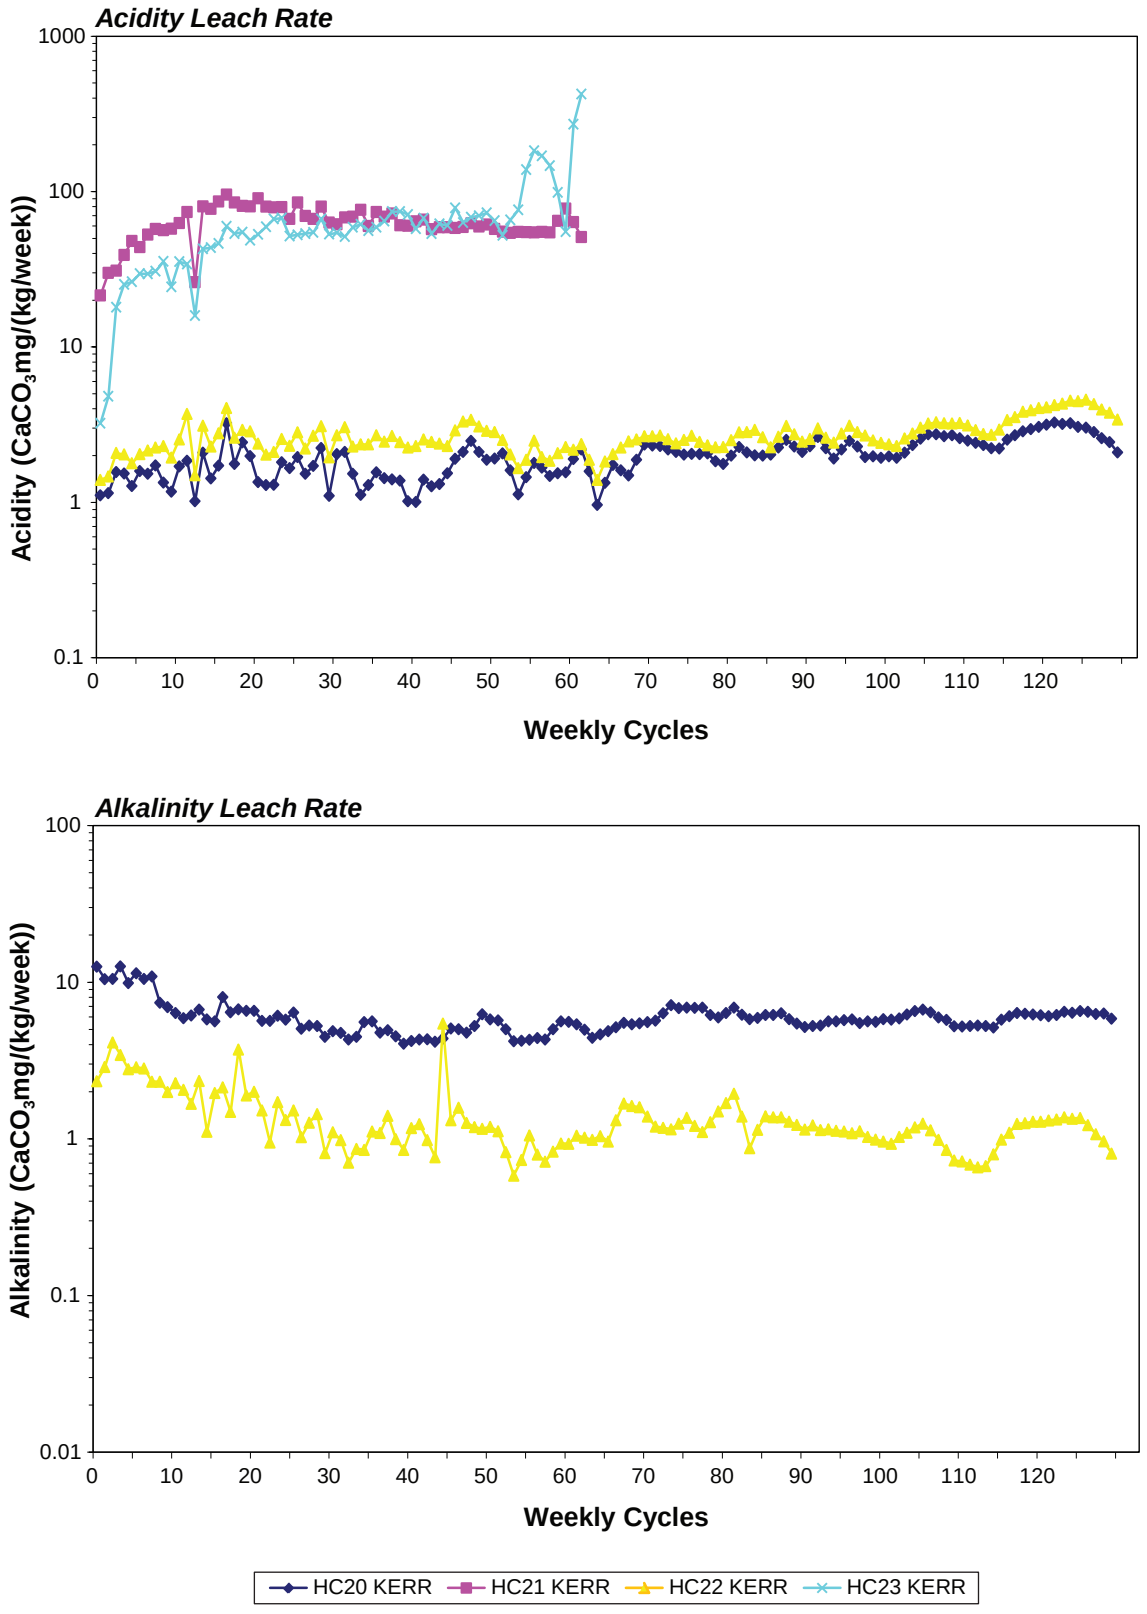
Aluminum and iron concentrations were controlled by leachate pH, with elevated concentrations in the acidic humidity cells. Aluminum leach rates in the near-neutral humidity cells decreased during the initial flush before stabilizing, and iron leach rates in the near-neutral humidity cells were highly variable. Aluminum leach rates in HC21 gradually decreased by week 61 to 0.4 mg/kg/wk. Iron leach rates in the acidic humidity cells increased for the first 16 weeks and then stabilized at 12 mg/kg/wk. Aluminum and iron leach rates sharply increased after week 51 in HC23, which was concomitant with the decrease in pH (Figure 5.2-8).

Manganese leach rates were generally stable in the near-neutral humidity cells and ranged from 0.02 to 0.03 mg/kg/wk. HC21 leach rates decreased for the first 12 weeks, increased sharply, and then stabilized at approximately 0.02 mg/kg/wk. HC23 leach rates increased at week 51, coincident with pH decreases (Figure 5.2-9).

Barium

Barium leach rates generally decreased over time for all humidity cells. A more rapid decrease in barium leach rates after cycle 51 for HC23 likely reflected increased barite precipitation due to increased sulphate production (Figure 5.2-9).

Trace Elements



In the near-neutral humidity cells, arsenic leach rates decreased to week 20 due to the initial flush and subsequent concentrations were frequently below detection. Steady state arsenic leach rates in HC21 were 0.02 mg/kg/wk. Arsenic leach rates were highly variably for HC23 until week 23 when rates substantially increased due to increased sulphide oxidation (Figure 5.2-10).

Cadmium concentrations were elevated in the acidic humidity cells relative to the near-neutral humidity cells. Steady state cadmium leach rates for the near-neutral humidity cells ranged from 0.00003 to 0.00013 mg/kg/wk. Steady state leach rates for the acidic humidity cells ranged from 0.0003 to 0.002 mg/kg/wk (Figure 5.2-10).

Chromium concentrations in the near-neutral humidity cells were frequently below detection. Chromium leach rates in HC21 decreased after week 40 and chromium leach rates in HC23 substantially increased after week 51 (Figure 5.2-11).

Stable cobalt leach rates in the near-neutral humidity cells ranged from 0.00007 mg/kg/wk in HC20 to 0.01 mg/kg/wk in HC22. HC21 leach rates were stable at 0.007 mg/kg/wk after an initial decrease. Cobalt leach rates in HC23 increased at week 51 with the decreased pH (Figure 5.2-11).

Copper leach rates in the acidic humidity cells were relatively stable over time at approximately 10 mg/kg/wk (Figure 5.2-12). Copper leach rates in the near-neutral HC22 gradually increased over time, while in the near-neutral HC20 copper leach rates reached a steady state rate of approximately 0.003 mg/kg/wk.

Figure 5.2-12

Rescan™
Engineers & Scientists

Fluoride concentrations in the near-neutral humidity cells and in the acidic HC21 were frequently below detection. Fluoride leach rates increased in HC23 after week 51 concomitant with the decrease in pH (Figure 5.2-12).

Lead concentrations in the acidic humidity cells were initially elevated relative to the near-neutral cells. Lead leach rates in all four humidity cells were highly variable over time (Figure 5.2-13).

Selenium concentrations were elevated in the acidic humidity cells relative to the near-neutral cells, and stabilized after approximately 20 weeks. Steady state selenium leach rates in the acidic humidity cells were approximately 0.007 mg/kg/wk and ranged from 0.0004 to 0.002 mg/kg/wk in the near-neutral humidity cells (Figure 5.2-13).

Silver concentrations in the near-neutral humidity cells were frequently below detection. Silver leach rates in the acidic humidity cells increased over time (Figure 5.2-14).

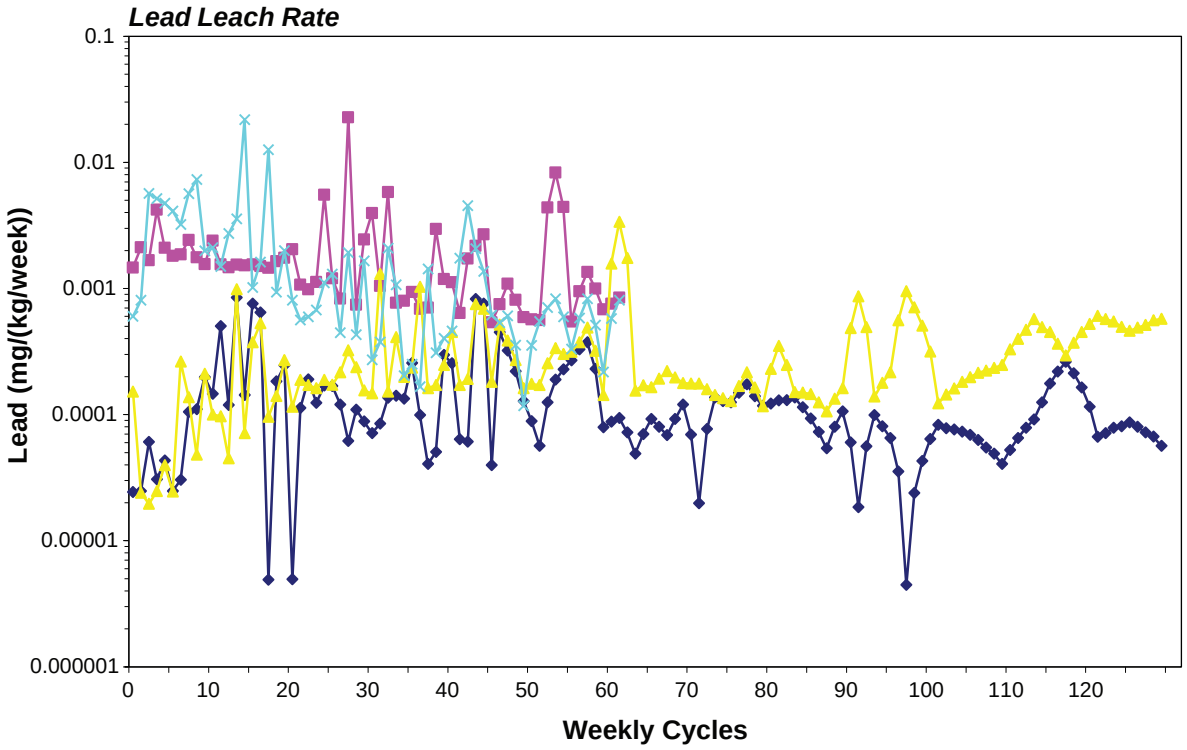
Zinc concentrations were elevated in the acidic humidity cells relative to the near-neutral cells. Leach rates in acidic HC21 gradually increased over time, while leach rates in HC 23 were more variable over time. Leach rates in the near-neutral humidity cells increased over time (Figure 5.2-14).

Table 5.2-2 summarizes the parameters with elevated concentrations by model code under acidic and neutral drainage conditions in order to inform treatment design.

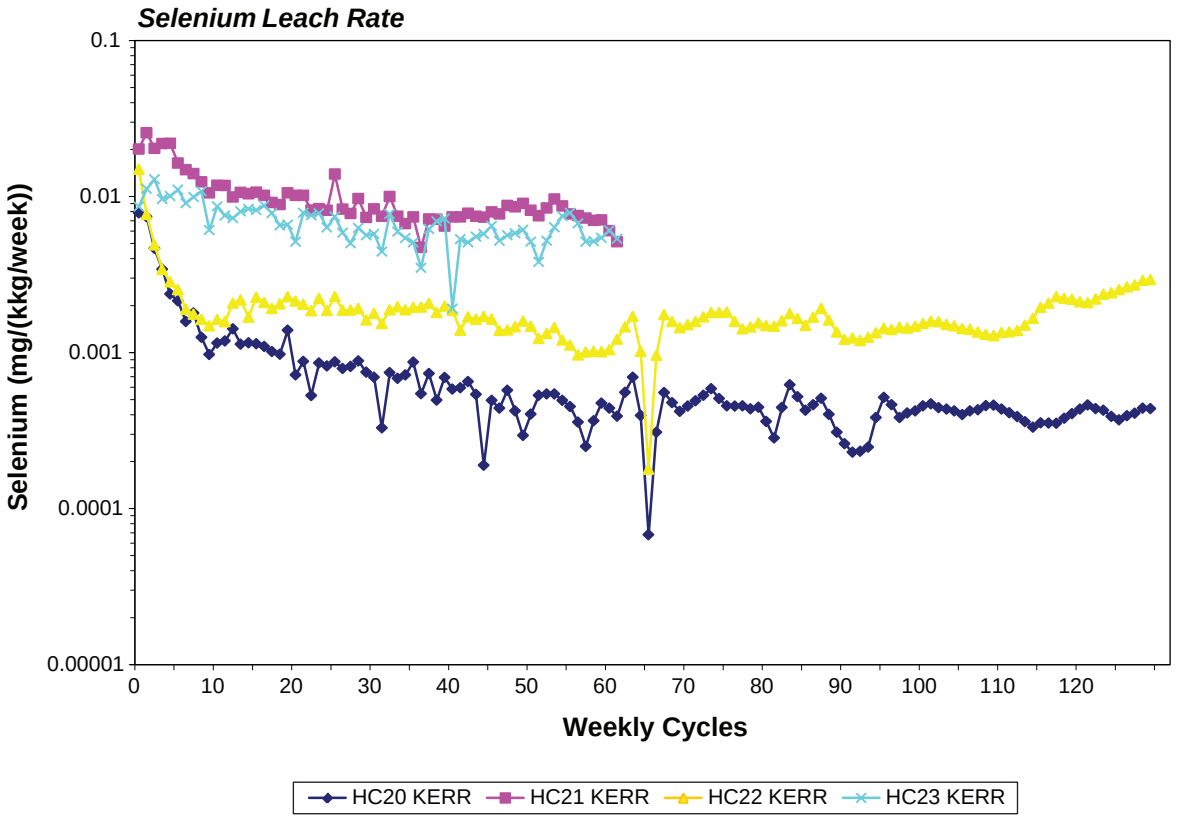
Table 5.2-2. Kerr Deposit Acidic and Neutral Leachate from Humidity Cells

Model Code	Acidic Drainage	Neutral Drainage
KERR	Sulphate, Aluminum, Arsenic, Cadmium, Chromium, Cobalt, Copper, Fluoride, Iron, Lead, Selenium, Silver, Zinc	Aluminum, Cadmium, Copper, Selenium

Elements Associated with the Neutralization Potential



In the near-neutral humidity cells, leach rates of calcium and magnesium were stable after an initial decrease, similar to the pH dynamics of the near-neutral humidity cells. The calcium and magnesium leach rates in the acidic humidity cells decreased over time, although rates in HC21 were more variable. Increased calcium and magnesium leach rates were observed after cycle 51 in HC23, concomitant with decreased pH and increased sulphate production (Figure 5.2-15).



Sulphurets Deposit

Seven humidity cells were operated for the Sulphurets Deposit for five ABA block model codes (two humidity cells for Lower Au Zone, two for UP Hazelton, one for Overburden, and two for Undefined) for between 56 and 179 weeks. The complete dataset for humidity cell leachate concentrations for the Sulphurets Deposit is presented in Appendix 5.2-4. The leach rates for additional parameters are presented in Appendix 5.2-3.

pH, Sulphate, Acidity, and Alkalinity

Six of the seven humidity cells from the Sulphurets Deposit had initial near-neutral pH and remained near-neutral through 56 to 129 cycles. One Overburden humidity cell (S-06-05) was initially acidic and the pH decreased to a stable pH between 2.5 to 2.7 (Figure 5.2-16).

Weekly pH and Sulphate Production Rates, Sulphurets Deposit Waste Rock Humidity Cells

Figure 5.2-16

Rescan™ Engineers & Scientists

Sulphate production rates decreased for approximately 20 cycles in the near-neutral humidity cells, representing the flushing of surface precipitates, before stabilizing between 1.2 to 8.5 mg/kg/wk. The pH and sulphate results indicated that any acid produced through sulphide oxidation in those near-neutral humidity cells was effectively neutralized. The acidic Overburden humidity cell had decreased rates of sulphate production for eight weeks, and subsequently sulphate concentrations gradually and variably increased from 8 to 112 weeks, indicating increased sulphide oxidation. Sulphate production rates slightly decreased from 112 to 179 weeks to a stable production rate of 142 mg/kg/wk (Figure 5.2-16).

Acidity production was highly variable and frequently below detection in the near-neutral humidity cells. After an initial one week decrease, acidity production increased over time in the acidic Overburden humidity cell, closely following the pH trend. Alkalinity production rates were stable in all humidity cells, with alkalinity in the near-neutral humidity cells between 9 to 11 mg/kg/wk, approximately an order of magnitude greater than in the acidic humidity cell (Figure 5.2-17).

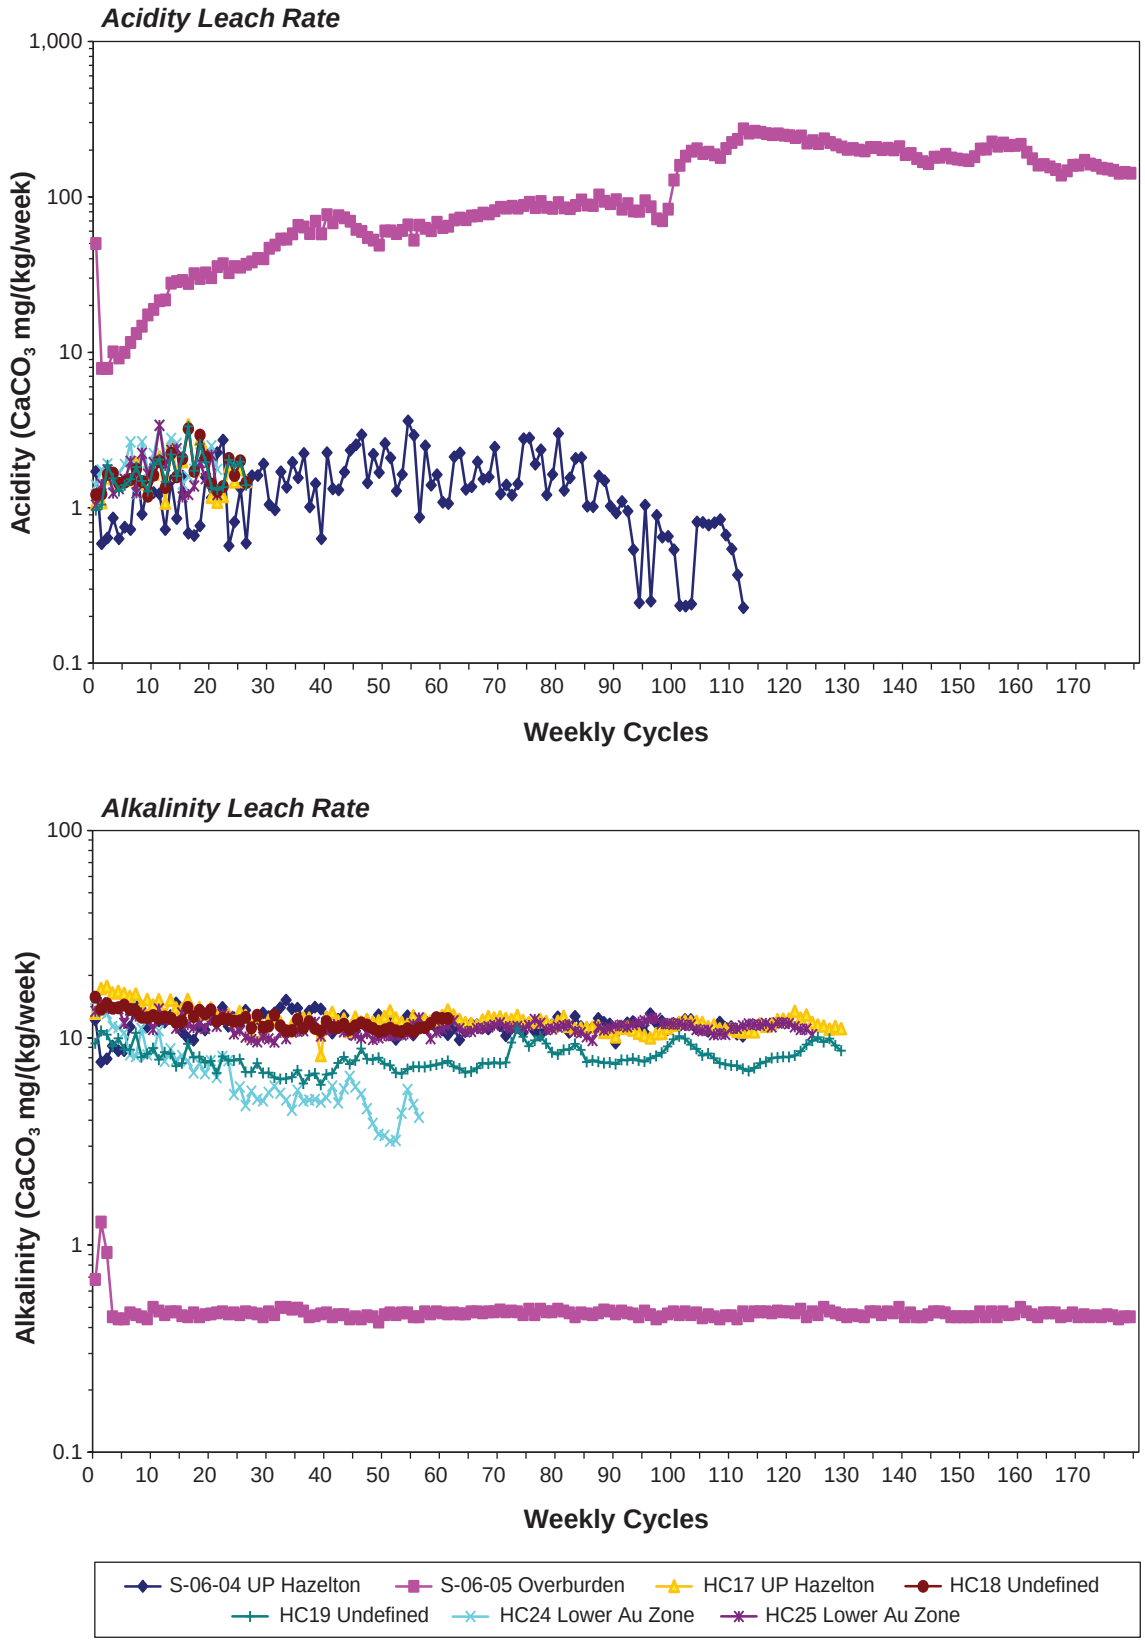
Elements that Contribute to Acidity

Aluminum and iron concentrations were controlled by leachate pH, with elevated concentrations in the acidic Overburden humidity cell. Aluminum and iron leach rates in the acidic Overburden humidity cell decreased during the initial flush before increasing variably. Near-neutral humidity cells' aluminum leach rates remained stable or decreased gradually over time (Figure 5.2-18). Iron leach rates in the near-neutral humidity cells were highly variable and frequently below detection (Figure 5.2-18).

Manganese leach rates decreased over time or were stable in all humidity cells (Figure 5.2-19).

Barium

Barium leach rates were stable over time for the near-neutral humidity cells between 0.007 to 0.08 mg/kg/wk. Barium leach rates were lower in the acidic Overburden humidity cell, likely due to increased barite precipitation due to increased sulphate production (Figure 5.2-19).



Trace Elements

Trace element concentrations were typically elevated in the acidic Overburden humidity cell relative to the near-neutral humidity cells, with the exception of lead. Notably, concentrations and leach rates of lead, cadmium, selenium, and zinc in HC19 Undefined were elevated relative to other near-neutral humidity cells and increasing.

Arsenic leach rates increased over time in the acidic Overburden humidity cell to approximately 0.03 mg/kg/wk in the last 10 weeks. A substantial increase in leach rates was observed at week 98 when the pH in the leachate decreased below 3.0. Arsenic leach rates in the near-neutral humidity cells were approximately an order of magnitude or more lower (Figure 5.2-20).

Cadmium leach rates were generally stable over time in the acidic Overburden humidity cell at 0.002 mg/kg/wk. In contrast, the near-neutral humidity cell cadmium leach rates were highly variable and concentrations were frequently below the detection limit. The exception to this trend was HC19 Undefined, in which cadmium leach rates increased over time to 0.004 mg/kg/wk (Figure 5.2-20).

Chromium leach rates in the acidic Overburden and the near-neutral UP Hazelton (S-06-04) humidity cells were similar and stable for 79 weeks, when the chromium concentrations in the MCMONZ leachate decreased to below the detection limit. The acidic Overburden chromium leach rates increased at week 98 in response to the decreased pH (pH < 3), and subsequently decreased for the remaining time. Chromium concentrations in the other near-neutral humidity cells were highly variable and frequently below the detection limit (Figure 5.2-21).

Chromium and Cobalt Leach Rates, Sulphurets Deposit Waste Rock Humidity Cells

Figure 5.2-21

Rescan™ Engineers & Scientists

Cobalt and copper leach rates were generally stable over time in the acidic Overburden humidity cell following an initial brief decrease during the first flush. Leach rates increased slightly when the leachate pH decreased below 3.0. Cobalt and copper concentrations in the near-neutral humidity cells were highly variable and frequently below the detection limit (Figures 5.2-21, 5.2-22).

Fluoride concentrations decreased to below the detection limit in all near-neutral humidity cells except HC25 Lower Au zone. Fluoride leach rates decreased in the acidic Overburden humidity cell for the first six weeks, gradually increased until week 100, and were variable for the following 79 weeks. Increased leach rates after week 100 likely reflect decreased pH in the Overburden leachate. The highest fluoride leach rates (0.25 mg/kg/wk) were observed in HC25 Lower Au zone and were stable over time (Figure 5.2-22).

Lead leach rates were generally low and variable or below the detection limit in all humidity cells except HC19 Undefined which had stable leach rates over time at 0.01 mg/kg/wk(Figure 5.2-23).

Selenium leach rates decreased over time for all near-neutral humidity cells. Selenium leach rates for HC19 Undefined (0.0008 mg/kg/wk) and the acidic Overburden (0.002 mg/kg/wk) humidity cells were elevated relative to the other humidity cells (Figure 5.2-23).

Molybdenum leach rates were elevated in HC 17 UP Hazelton over all Sulphurets humidity cells at 0.09 mg/kg/wk. Molybdenum leach rates in the other humidity cells were orders of magnitude lower and frequently below detection (Figure 5.2-24).

Nickel leach rates were elevated in the acidic S-06-05 Overburden over all Sulphurets humidity cells at 0.02 mg/kg/wk. Nickel leach rates in the other humidity cells were orders of magnitude lower and frequently below detection (Figure 5.2-24).

Zinc leach rates gradually decreased over time in the acidic Overburden humidity cell to 0.5 mg/kg/wk. The leach rates in the near-neutral humidity cells were typically four orders of magnitude lower, and concentrations in HC25 Lower Au zone and HC17 UP Hazelton were frequently below detection. Zinc leach rates increased over time in HC19 Undefined to 0.09 mg/kg/wk (Figure 5.2-25).

Table 5.2-3 summarizes the parameters with elevated concentrations by model code under acidic and neutral drainage conditions in order to inform treatment design.

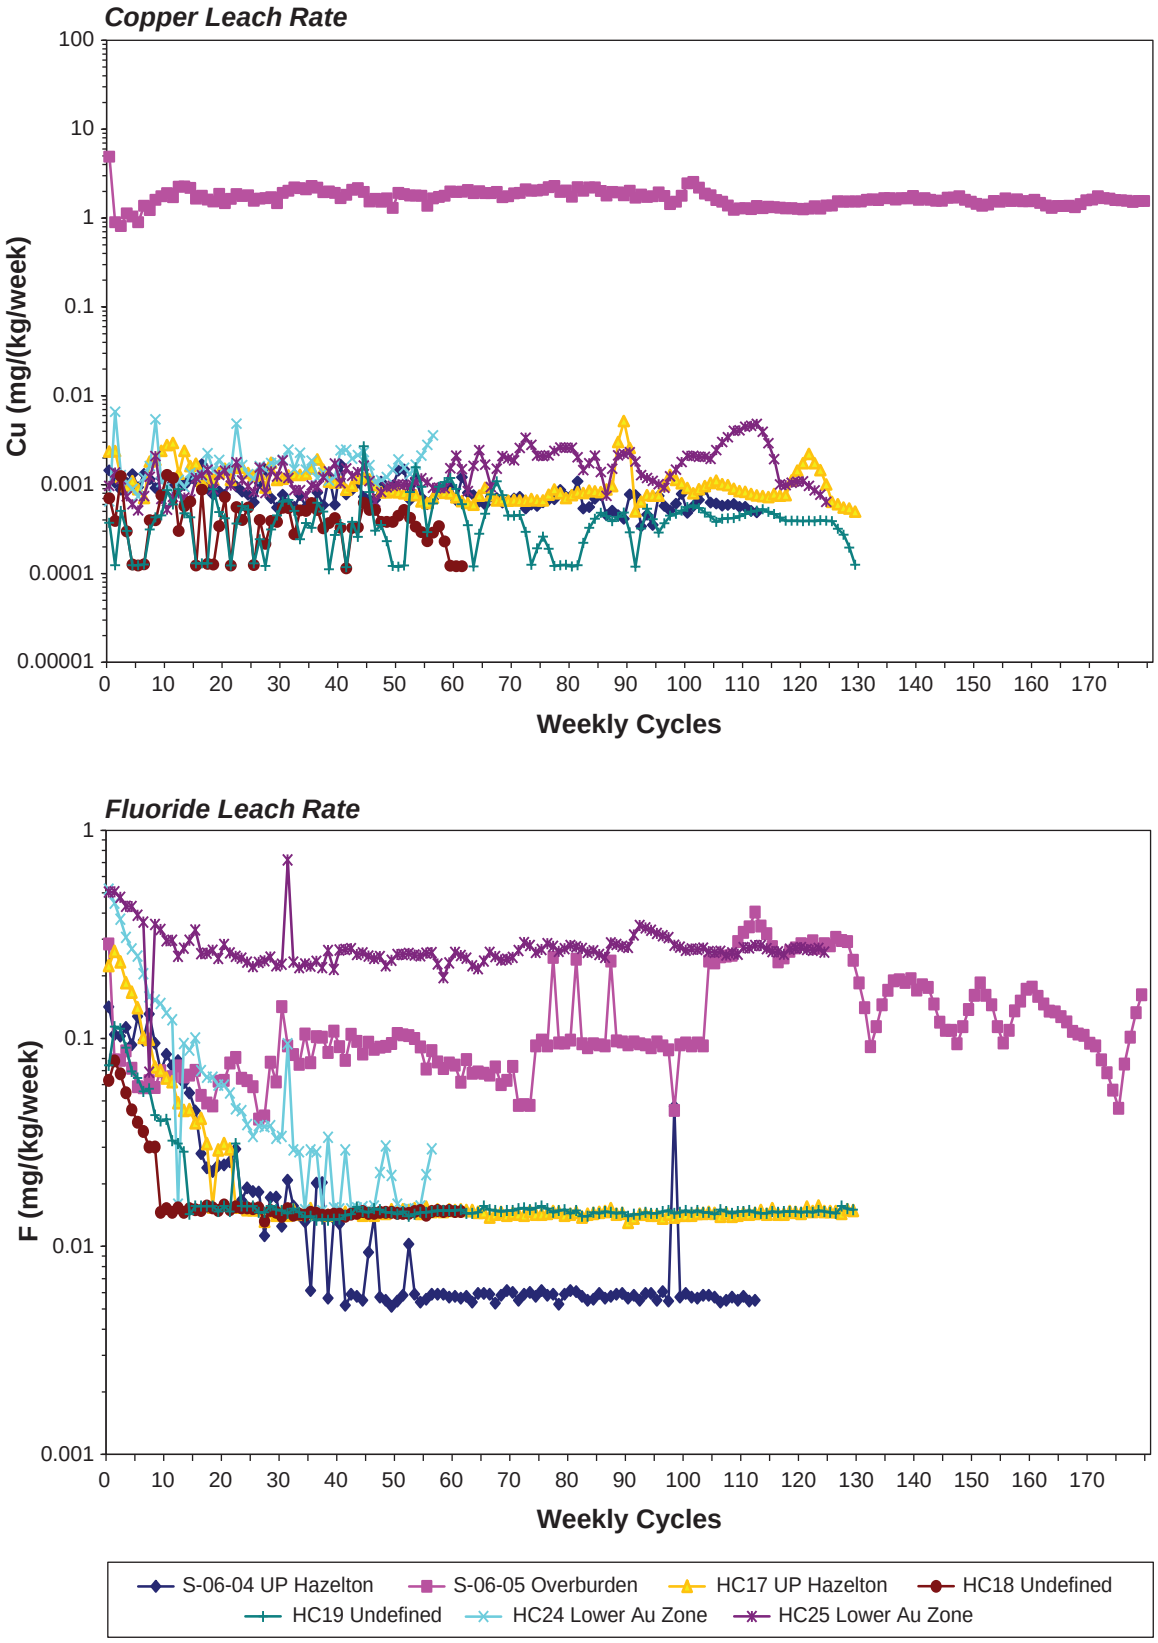

Table 5.2-3. Sulphurets Deposit Acidic and Neutral Leachate from Humidity Cells

Model Code	Acidic Drainage	Neutral Drainage
Overburden	Sulphate, Aluminum, Arsenic, Cadmium, Chromium, Cobalt, Copper, Fluoride, Iron, Nickel, Selenium, Zinc	n/a
UP Hazelton	n/a	Aluminum, Cadmium, Copper, Molybdenum
Lower Au Zone	n/a	Cadmium, Copper, Fluoride
Undefined	n/a	Aluminum, Cadmium, Lead, Selenium, Zinc

n/a indicates that no humidity cell was observed.

Elements Associated with the Neutralization Potential

Calcium and magnesium leach rates have been decreasing over time indicating that neutralization potential is likely being consumed. Increased calcium and magnesium leach rates at week 98 corresponded to the pH decrease below 3.0 in the acidic Overburden humidity cell (Figure 5.2-26).

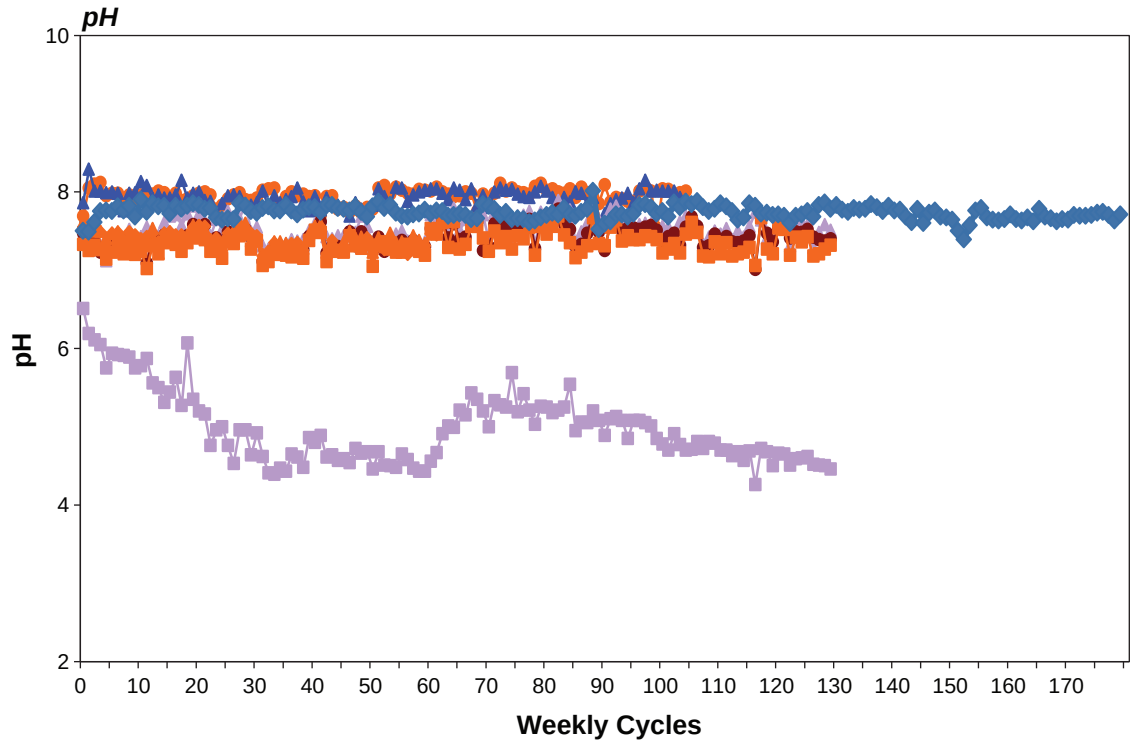
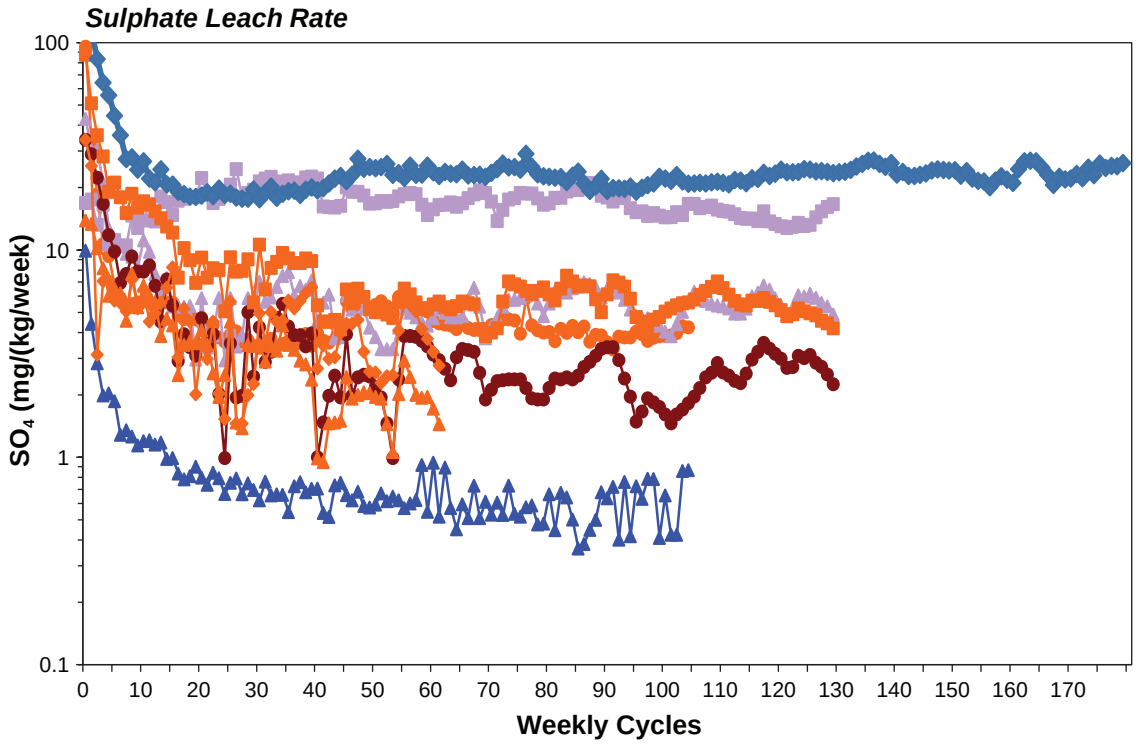
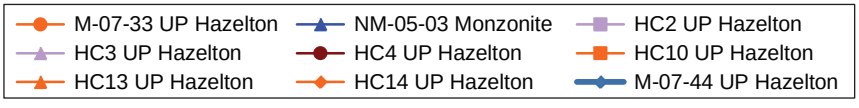
Mitchell Deposit



Twenty-three humidity cells were operated for the Mitchell Deposit from the upper panel (UP; above the MTF) and the lower panel (LP; below the MTF). Nine humidity cells were operated representing the upper panel and 16 humidity cells represent the lower panel. The Mitchell upper panel humidity cells were operated for between 61 and 179 weeks and represent two ABA block model codes with eight humidity cells representing UP Hazelton and one humidity cell representing Monzonite. The Mitchell lower panel humidity cells were operated for between 61 and 129 weeks and represent three model codes with 12 humidity cells representing LP Hazelton, and one humidity cell representing each of Monzonite and Leach breccia/bornite breccia. The leachate chemistry of the lower panel Mitchell Deposit humidity cells was observed to have higher element concentrations in general. The complete dataset for Mitchell Deposit humidity cell leachate concentrations is presented in Appendix 5.2-5. The leach rates for additional parameters are presented in Appendix 5.2-3.



pH, Sulphate, Acidity, and Alkalinity



Seven of the nine upper panel humidity cells had initial near-neutral pH and remained near-neutral through 61 to 179 weekly cycles (Figure 5.2-27). HC2 UP Hazelton had an initial pH of 6.51 and decreased to pH 4.43 by week 59, and subsequently increased to maximum of pH 5.69 at week 74, and then decreased for the remaining weeks. Eleven of the 14 lower panel humidity cells had initial near-neutral pH and 10 remained near neutral through 61 to 129 weekly cycles (Figure 5.2-27). HC1 LP Hazelton had an initial pH of 6.57 and decreased to approximately pH 3 by week 15. Two other LP Hazelton humidity cells (M-06-14 and M-07-43) had initial acidic pH values and remained acidic throughout the operating weeks. HC15 Leach breccia/bornite breccia also had an acidic initial pH and had the lowest steady-state pH of less than pH 2.5.

Sulphate production rates decreased initially in all upper and lower panel humidity cells representing the flushing of surface precipitates. In the upper panel humidity cells, the acidic HC2 UP Hazelton and the near-neutral M-07-44 UP Hazelton had the highest steady-state production rates, ranging from 13-27 mg/kg/wk. The lowest sulphate production rates were two orders of magnitude lower in the NM-05-03 Monzonite humidity cell (Figure 5.2-27). In the lower panel humidity cells, sulphate production rates were ordered by model code from greatest to lowest as Leach breccia/bornite breccia > LP Hazelton > Monzonite (Figure 5.2-28). Sulphate production rates increased rapidly in HC15 Leach breccia/bornite breccia between weeks 15 and 25 by an order of magnitude. Sulphate production rates in the LP Hazelton humidity cells were stable after the initial decrease and ranged from 2.5 to 180 mg/kg/wk after 100 weeks.

Acidity and alkalinity production rates followed pH trends in upper panel humidity cells. Increased acidity production was observed in HC2 UP Hazelton as pH decreased. Stable acidity production rates were approximately an order of magnitude lower in the near-neutral upper panel humidity cells (Figure 5.2-29). Alkalinity production in HC2 UP Hazelton decreased to below the detection limit at week 29, but then increased when pH increased after week 60. Alkalinity production subsequently decreased in HC2 below detection after 100 weekly cycles. Acidity production rates in HC15 Leach breccia/bornite breccia and M-07-43 LP Hazelton humidity cells increased concomitant with pH decreases. Acidity production in acidic lower panel humidity cells was one to three orders of magnitude greater than in near-neutral humidity cells (Figure 5.2-30). Alkalinity production was approximately an order of magnitude greater in near-neutral lower panel humidity cells than in the acidic M-07-43 and M-06-14 LP Hazelton humidity cells. Alkalinity was below the detection limit in the other acidic lower panel humidity cells (HC 15 and HC1.

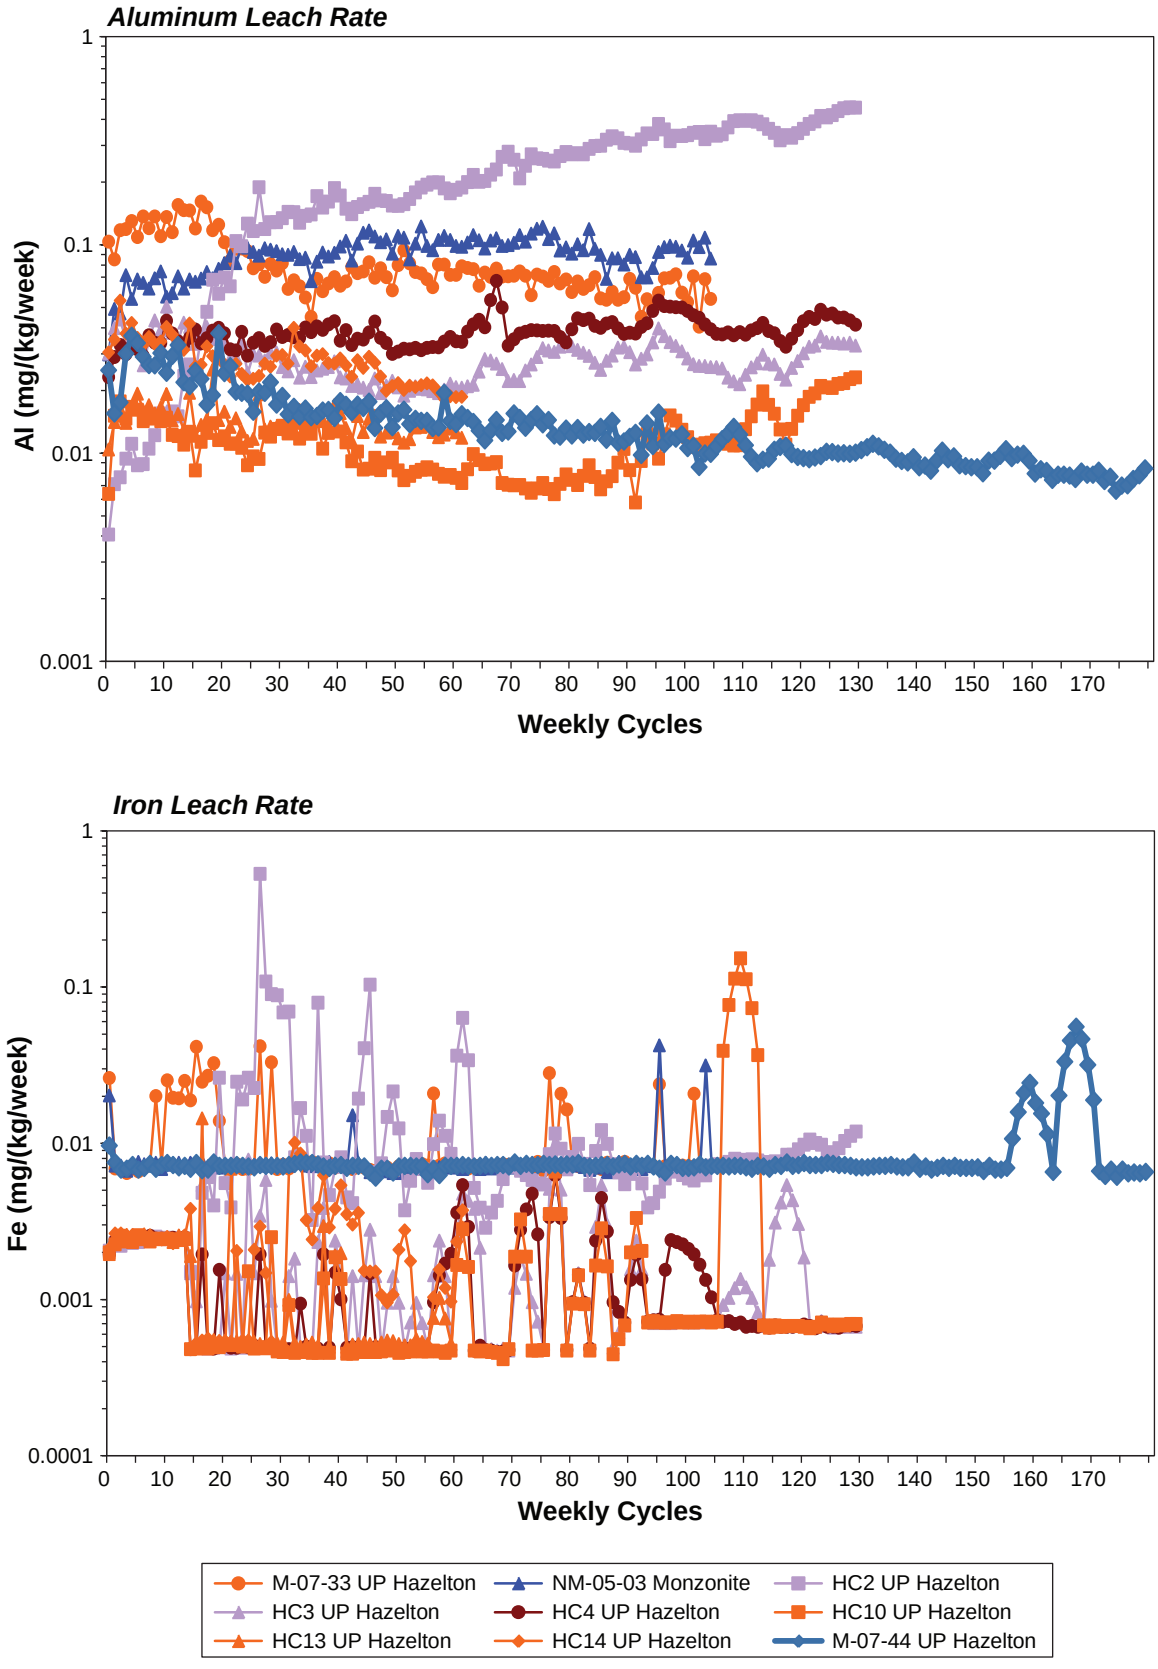
Elements that Contribute to Acidity

Aluminum concentrations in upper panel humidity cells reflected leachate pH. The acidic UP Hazelton humidity cell had elevated leachate concentrations relative to other upper panel humidity cells. Near-neutral aluminum leach rates ranged from 0.008 to 0.1 mg/kg/wk. Aluminum leach rates in all lower panel humidity cells closely followed pH trends with the timing of increased rates coinciding with decreases in pH (Figures 5.2-31, 5.2-32).

Upper panel iron leach rates were highly variable and frequently below the detection limit. Iron leach rates were pH-dependent with increases in iron leach rates for HC 1 LP Hazelton, M-07-43 LP Hazelton, and HC 15 Leach breccia/bornite breccia occurring simultaneously with decreases in pH. Iron leach rates from the lower panel Monzonite humidity cell were greater than iron leach rates from other near-neutral LP Hazelton humidity cells. The near-neutral lower panel humidity cells typically had highly variable iron leach rates and concentrations occasionally below the detection limit (Figures 5.2-31, 5.2-32).

Manganese leach rates also typically reflected leachate pH, with greater concentrations in the acidic HC2 relative to other near-neutral upper panel humidity cells by one to two orders of magnitude (Figure 5.2-33). The near-neutral upper panel leach rates ranged from 0.0027 to 0.17 mg/kg/wk. HC15 Leach breccia/bornite breccia manganese leach rates were greater than LP Hazelton leach rates (Figure 5.2-34).

Barium



Barium leach rates were generally stable over time in all upper panel and near-neutral lower panel humidity cells. Decreasing barium leach rates in HC 14 UP Hazelton, HC15 Leach breccia/bornite breccia, and M-06-14 LP Hazelton humidity cells were observed (Figures 5.2-33, 5.2-34).

Trace Elements

Antimony leach rates in M-07-44 UP Hazelton were elevated relative to other upper panel humidity cells at approximately 0.10 mg/kg/wk and remained relatively constant throughout the 179 weekly cycles. Antimony leach rates for all other humidity cells were more than an order of magnitude less and were stable or decreasing (Figure 5.2-35), with the exception of HC2, HC4 and HC3 UP Hazelton which had variable release rates.

The arsenic leach rates in M-07-44 UP Hazelton were elevated relative to both acidic and near-neutral upper panel humidity cells, remaining stable over time at approximately 0.003 mg/kg/wk. The leach rates for HC15 Leach breccia/bornite breccia sharply increased with the decrease in pH below 3 at week 16. The steady state leach rate in HC15 Leach breccia/bornite breccia was approximately 0.06 mg/kg/wk. Leach rates in all other humidity cells were stable or decreasing and were one or more orders of magnitude lower (Figure 5.2-36).

The greatest upper panel cadmium leach rates were observed in UP Hazelton HC 2, HC 10, and M-07-44 and ranged from 0.00016 to 0.00073 mg/kg/wk. The cadmium release rates from UP Hazelton HC 3 and HC 4 sharply increased at week 104 to 0.0025 and 0.011 mg/kg/wk, respectively, at week 109, and the release rates decreased to below detection in subsequent weeks. Cadmium leach rates in the other upper panel humidity cells were highly variable and frequently below detection. The highest lower panel cadmium leach rates of 0.002 mg/kg/wk were observed in the LP Hazelton M-06-14 humidity cell. Leach rates in other acidic lower panel humidity cells were generally stable over time with increases in rates typically reflecting leachate pH falling below 3 (Figure 5.2-37).

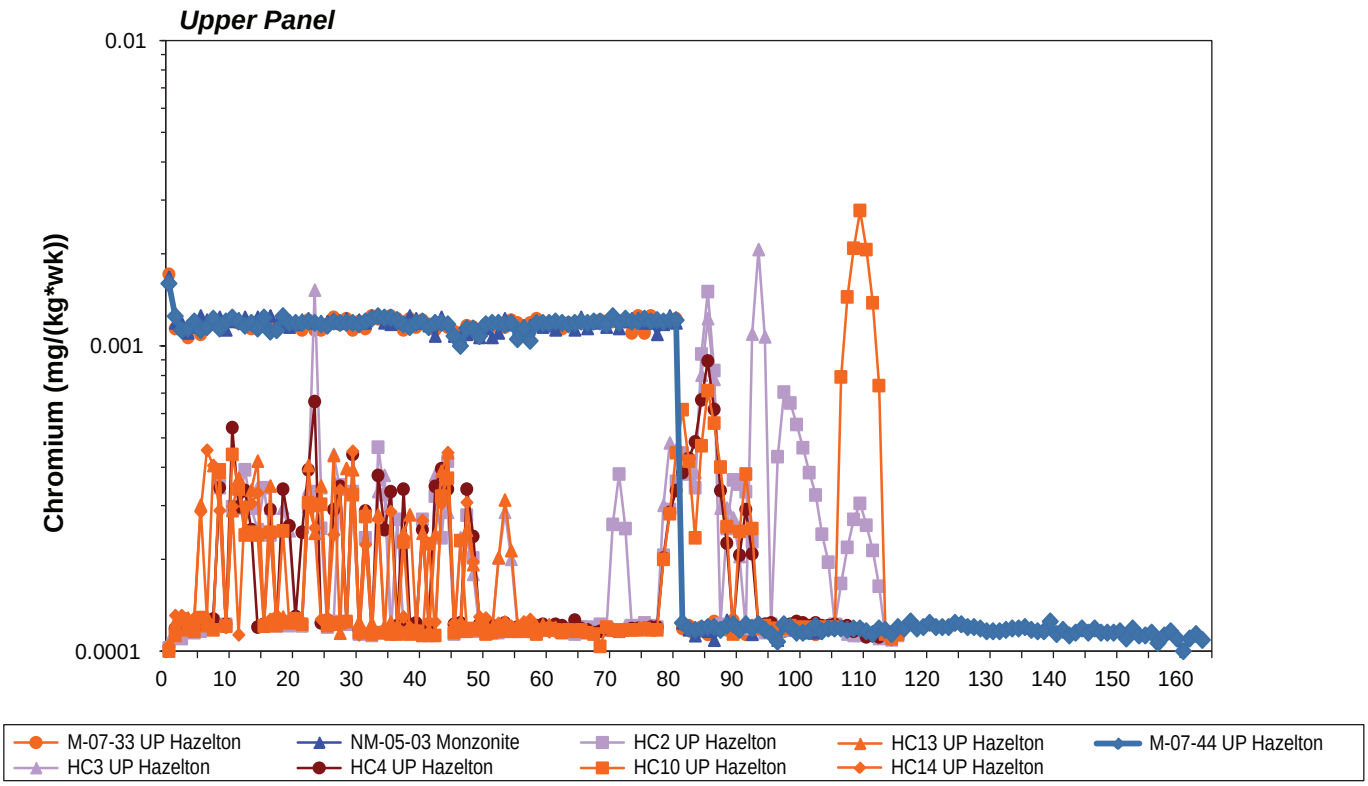
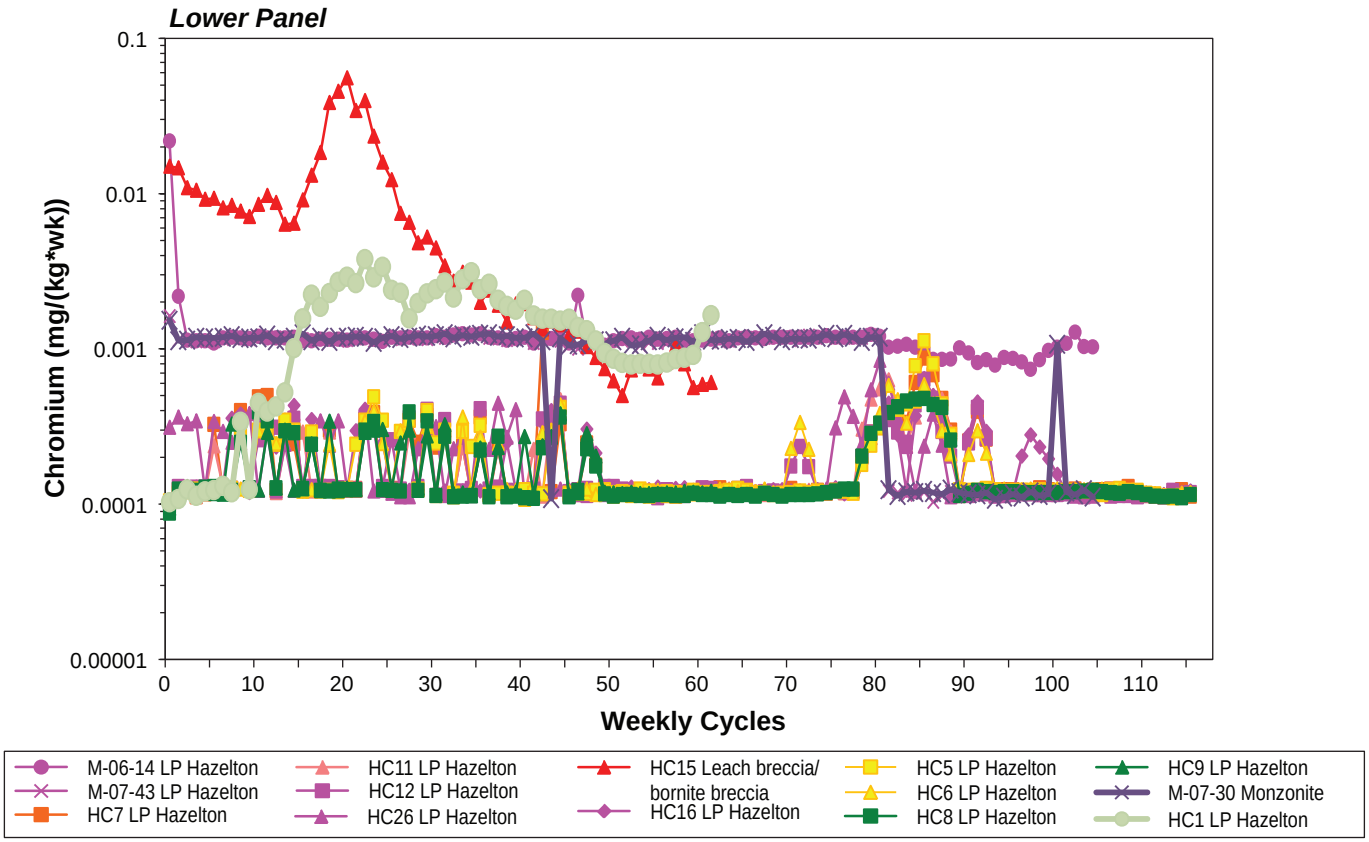
Chromium concentrations in upper panel humidity cells were highly variable and frequently below detection. Chromium leach rates in HC15 Leach breccia/bornite breccia increased with the decrease in pH below 3 at week 16, but subsequently decreased for the remaining weeks. Leach rates HC 1 LP Hazelton fluctuated around 0.01 mg/kg/wk in the last 10 weeks of testing. Chromium concentrations in the other lower panel humidity cells were frequently below detection (Figure 5.2-38).

Cobalt leach rates in the acidic HC3 UP Hazelton and the near-neutral HC14 UP Hazelton were elevated with steady state rates of 0.023 and 0.006 mg/kg/wk, respectively. Cobalt leach rates increased in HC15 Leach breccia/bornite breccia increased when the pH dropped below 3 to a steady state rate of 0.05 mg/kg/wk. Other acidic lower panel humidity cells ranged from 0.0064 to 0.012 mg/kg/wk. Leach rates in the near-neutral humidity cells ranged from 0.00001 to 0.00034 mg/kg/wk (Figures 5.2-39).

Copper leach rates were elevated in the acidic HC2 UP Hazelton by greater than three orders of magnitude relative to the near-neutral upper panel humidity cells, with a steady state leach rate of 4.5 mg/kg/wk. The near- neutral upper panel humidity cells steady state leach rates ranged from 0.01 to 0.002 mg/kg/wk, although a high degree of variability was observed in HC3 UP Hazelton. Copper concentrations in M-07-33 UP Hazelton humidity cell were frequently below detection. Steady state leach rates in the three acidic LP Hazelton humidity cells ranged from 0.5 to 2 mg/kg/wk. Copper concentrations increased to week 16 in HC15 Leach breccia/bornite breccia and then decreased to a steady state leach rate of 0.09 mg/kg/wk. The near-neutral lower panel copper leach rates ranged from 0.0002 to 0.004 mg/kg/wk (Figures 5.2-40).



Fluoride leach rates were elevated in the acidic HC2 UP Hazelton and the near-neutral HC 4 and HC 10 UP Hazelton, and in the LP Hazelton (M-06-14, M-07-43, and HC 7) and HC 15 Leach breccia/bornite breccia humidity cells. Fluoride leach rates in the other near-neutral upper panel and lower panel humidity cells decreased over time until concentrations were below the detection limit. Acidic humidity cells from both the upper and lower panel had similar steady-state fluoride leach rates between 0.2 to 0.4 mg/kg/wk (Figures 5.2-41).



Lead leach rates were highly variable in the acidic HC2 UP Hazelton and were stable from week 4 in HC10 UP Hazelton at 0.01 mg/kg/wk. Highly variable leach rates with concentrations frequently below detection were observed in the other near-neutral upper panel humidity cells. Leach rates in the two acidic LP Hazelton humidity cells decreased for the last 30 to 50 weeks to between 0.01 to 0.07 mg/kg/wk. The steady state leach rate in HC15 Leach breccia/bornite breccia lower panel was 0.006 mg/kg/wk (Figures 5.2-42).

Selenium leach rates in the UP Hazelton humidity cells ranged from 0.00025 to 0.017 mg/kg/wk. Steady state selenium leach rates in the LP Hazelton humidity cells ranged from 0.00001 to 0.0023 mg/kg/wk. HC15 Leach breccia/bornite breccia leach rates increased at week 16 with the decrease in pH and stabilized at 0.08 mg/kg/wk (Figure 5.2-43).

Silver leach rates in the HC15 Leach breccia/bornite breccia increased over time to 0.0006 mg/kg/wk in the last 10 weeks. The leach rates in the other humidity cells were variable, orders of magnitude lower, and frequently below the detection limit (Figure 5.2-44).

Vanadium concentrations were frequently below detection in upper panel humidity cells. Vanadium concentrations were elevated in M-06-14 LP Hazelton and HC15 Leach breccia/bornite breccia with leach rates of 0.005 to 0.008 mg/kg/wk. All other lower panel humidity cells had decreasing leach rates or concentrations below detection (Figure 5.2-45).

Zinc leach rates were elevated in the acidic HC2 UP Hazelton, and the near-neutral HC10 UP Hazelton, and M-07-44 UP Hazelton with leach rates ranging from 0.0035 to 0.030 mg/kg/wk. Among the acidic lower panel humidity cells, steady state leach rates humidity cells ranged from 0.021 to 0.23 mg/kg/wk (Figure 5.2-46).

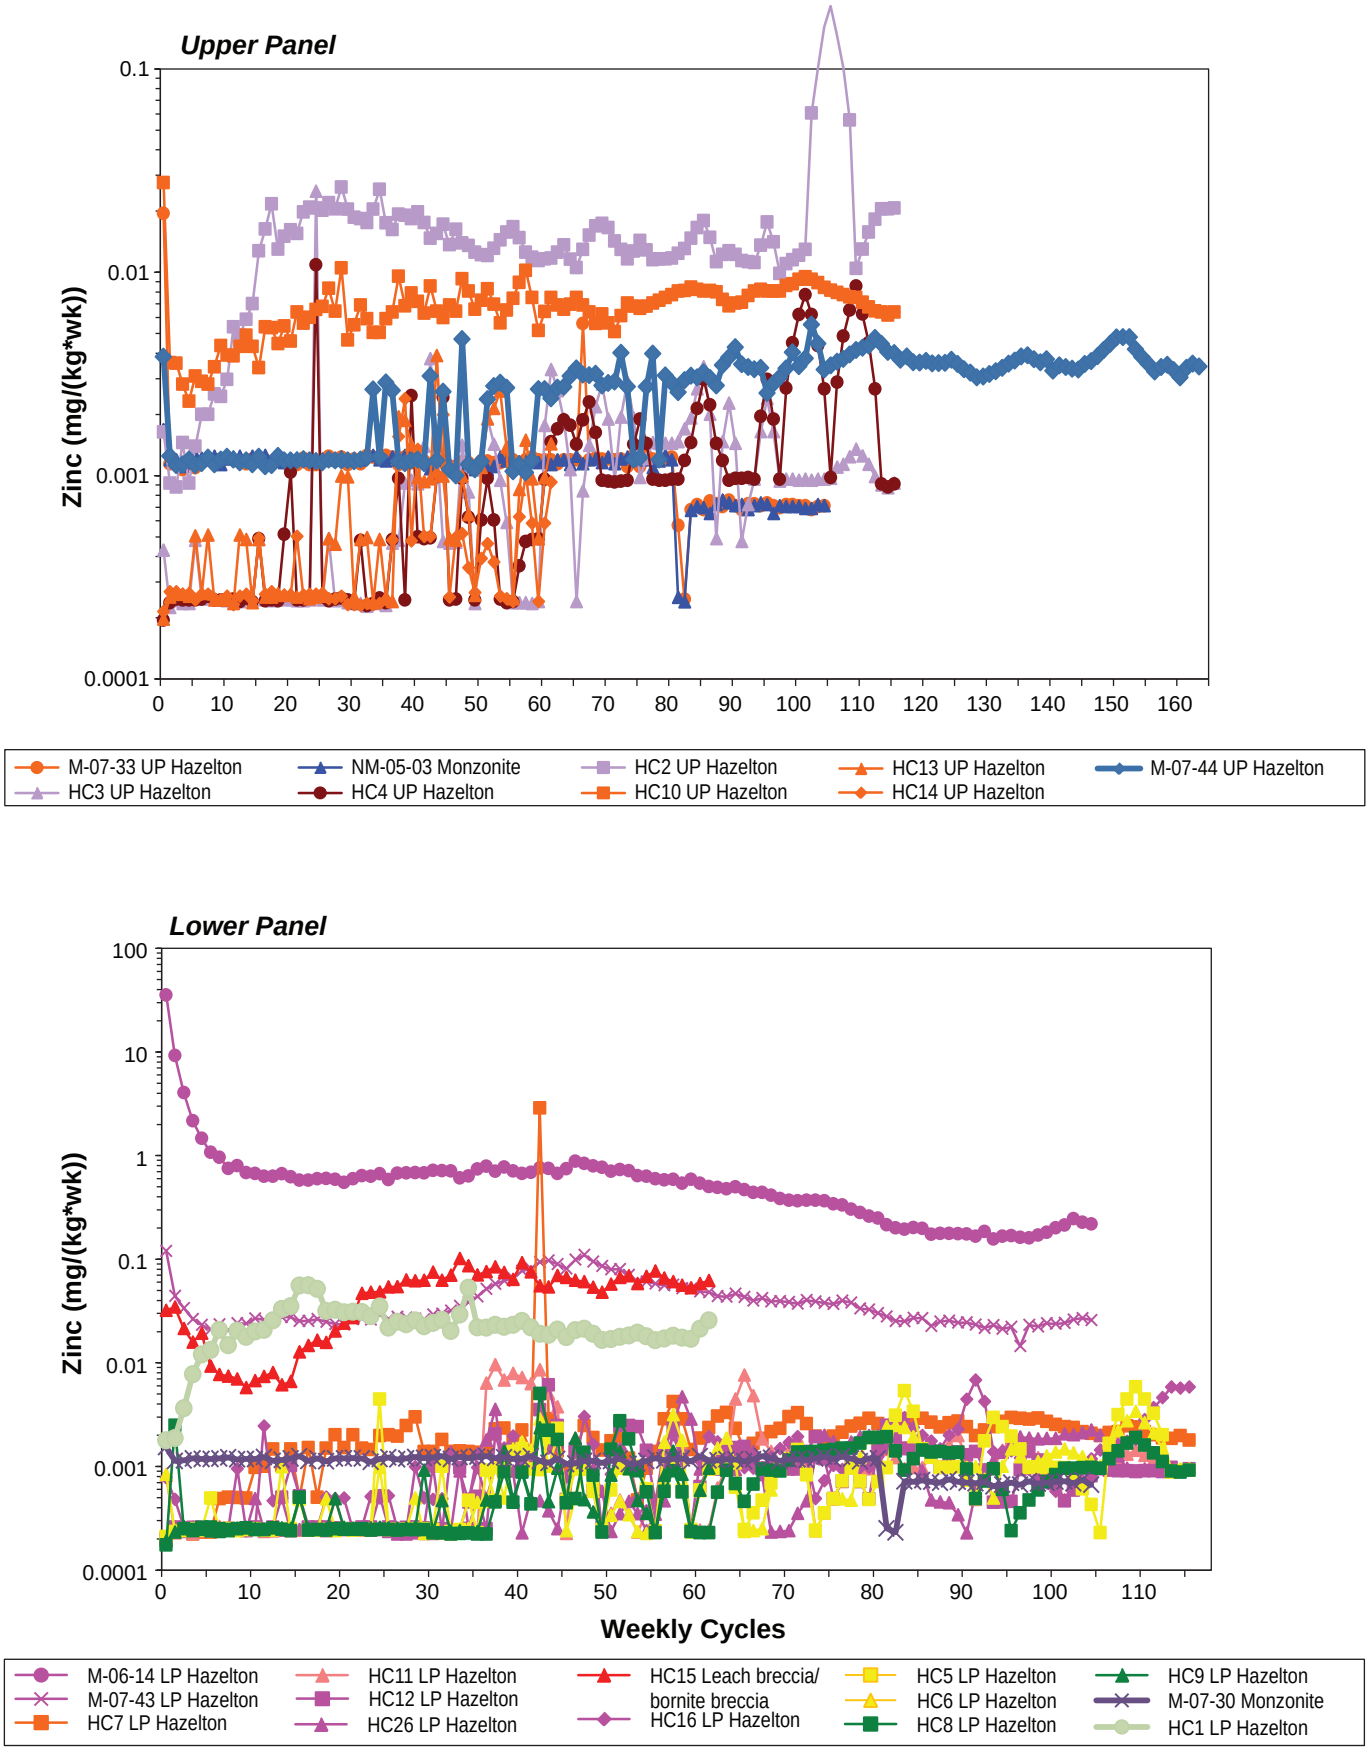
Table 5.2-4 summarizes the parameter with elevated concentrations by model code under acidic and neutral drainage conditions in order to inform treatment design.

Table 5.2-4. Mitchell Deposit Acidic and Neutral Leachate from Humidity Cells

Model Code	Acidic Drainage	Neutral Drainage
Upper panel		
UP Hazelton	Aluminum, Cadmium, Copper, Fluoride, Lead, Manganese, Selenium, Silver, Zinc	Aluminum, Antimony, Arsenic, Cadmium, Chromium, Cobalt, Copper, Fluoride, Lead, Selenium
Monzonite	n/a	Aluminum, Cadmium, Copper
Lower panel		
LP Hazelton	Sulphate, Aluminum, Cadmium, Chromium, Cobalt, Copper, Fluoride, Iron, Lead, Manganese, Selenium, Silver, Vanadium, Zinc	Aluminum, Cadmium, Copper, Fluoride, Selenium
Leach breccia/bornite breccia	Sulphate, Aluminum, Arsenic, Cadmium, Chromium, Cobalt, Copper, Fluoride, Iron, Lead, Selenium, Silver, Vanadium, Zinc	n/a
Monzonite	n/a	Cadmium

n/a indicates that no humidity cell was observed.

Elements associated with the Neutralization Potential



Calcium and magnesium leach rates in the acidic HC2 UP Hazelton steadily decreased through week 99 indicating consumption of neutralization potential. Calcium continued to decrease through week 129, while magnesium increased from week 99 to week 129, suggesting silicate mineral assemblages possibly contributed to acid neutralization. Calcium leach rates in the near-neutral upper panel humidity cells were stable over time, while magnesium leach rates decreased over time with the exception of M-07-33 UP Hazelton and M-07-44 UP Hazelton. Calcium and magnesium leach rates were typically stable or gradually decreased over time in lower panel humidity cells. Leach rates in HC15 Leach breccia/bornite breccia lower panel sharply increased at week 16 when pH decreased (Figures 5.2-47, 5.2-48).

Iron Cap Deposit

Six humidity cells of the ABA block model code Iron Cap were operated for 75 weeks to the cut-off date for data for this report. The complete dataset for humidity cell leachate concentrations for the Iron Cap deposit is presented in Appendix 5.2-6. The leach rates for additional parameters are presented in Appendix 5.2-3.

pH, Sulphate, Acidity, and Alkalinity

Three of the six Iron Cap humidity cells were acidic (HCT-3, 4, and 6) and three remained near-neutral (HCT-1, 2, and 5) throughout the 75 weekly cycles. Observed pH decreased steadily over the 75 weeks in HC-3 and HC-6 acidic cells to 2.80. The pH in HC-4 steady decreased over 55 weeks to around 4, and sharply decreased through week 70 to pH 2.80 (Figure 5.2-49).

Weekly pH and Sulphate Production Rates, Iron Cap Deposit Waste Rock Humidity Cells

Figure 5.2-49

Rescan™ Engineers & Scientists

Sulphate production rates in HCT-3 and HCT-6 increased after week 30 to between 70 to 100 mg/kg/wk. The sulphate production rate in HCT-4 increased with the decrease in pH after week 55 from approximately 8 mg/kg/wk to 90 mg/kg/wk by week 70. Sulphate production rates decreased over 37 weeks in the other 4 humidity cells and stabilized between 6.5 to 11 mg/kg/wk (Figure 5.2-49).

Acidity was frequently below detection in the near-neutral humidity cells. Acidity production rates increased sharply after week 25 in HCT-6. The acidity production rate in HC-4 steadily increased after week 50 to a similar production rate observed in other acidic humidity cells (100 mg $CaCO_3$/kg/wk). Alkalinity was frequently below detection after week 10 in the acidic humidity cells and alkalinity production was stable at 4.9 to 11 mg $CaCO_3$/kg/wk in the three near-neutral humidity cells (Figure 5.2-50).

Elements that Contribute to Acidity

Aluminum leach rates were relatively stable over time in the near-neutral humidity cells, ranging between 0.01 and 0.04 mg/kg/wk. Aluminum leach rates increased to steady state rates between 1.2 to 3.3 mg/kg/wk in the acidic humidity cells (Figure 5.2-51).

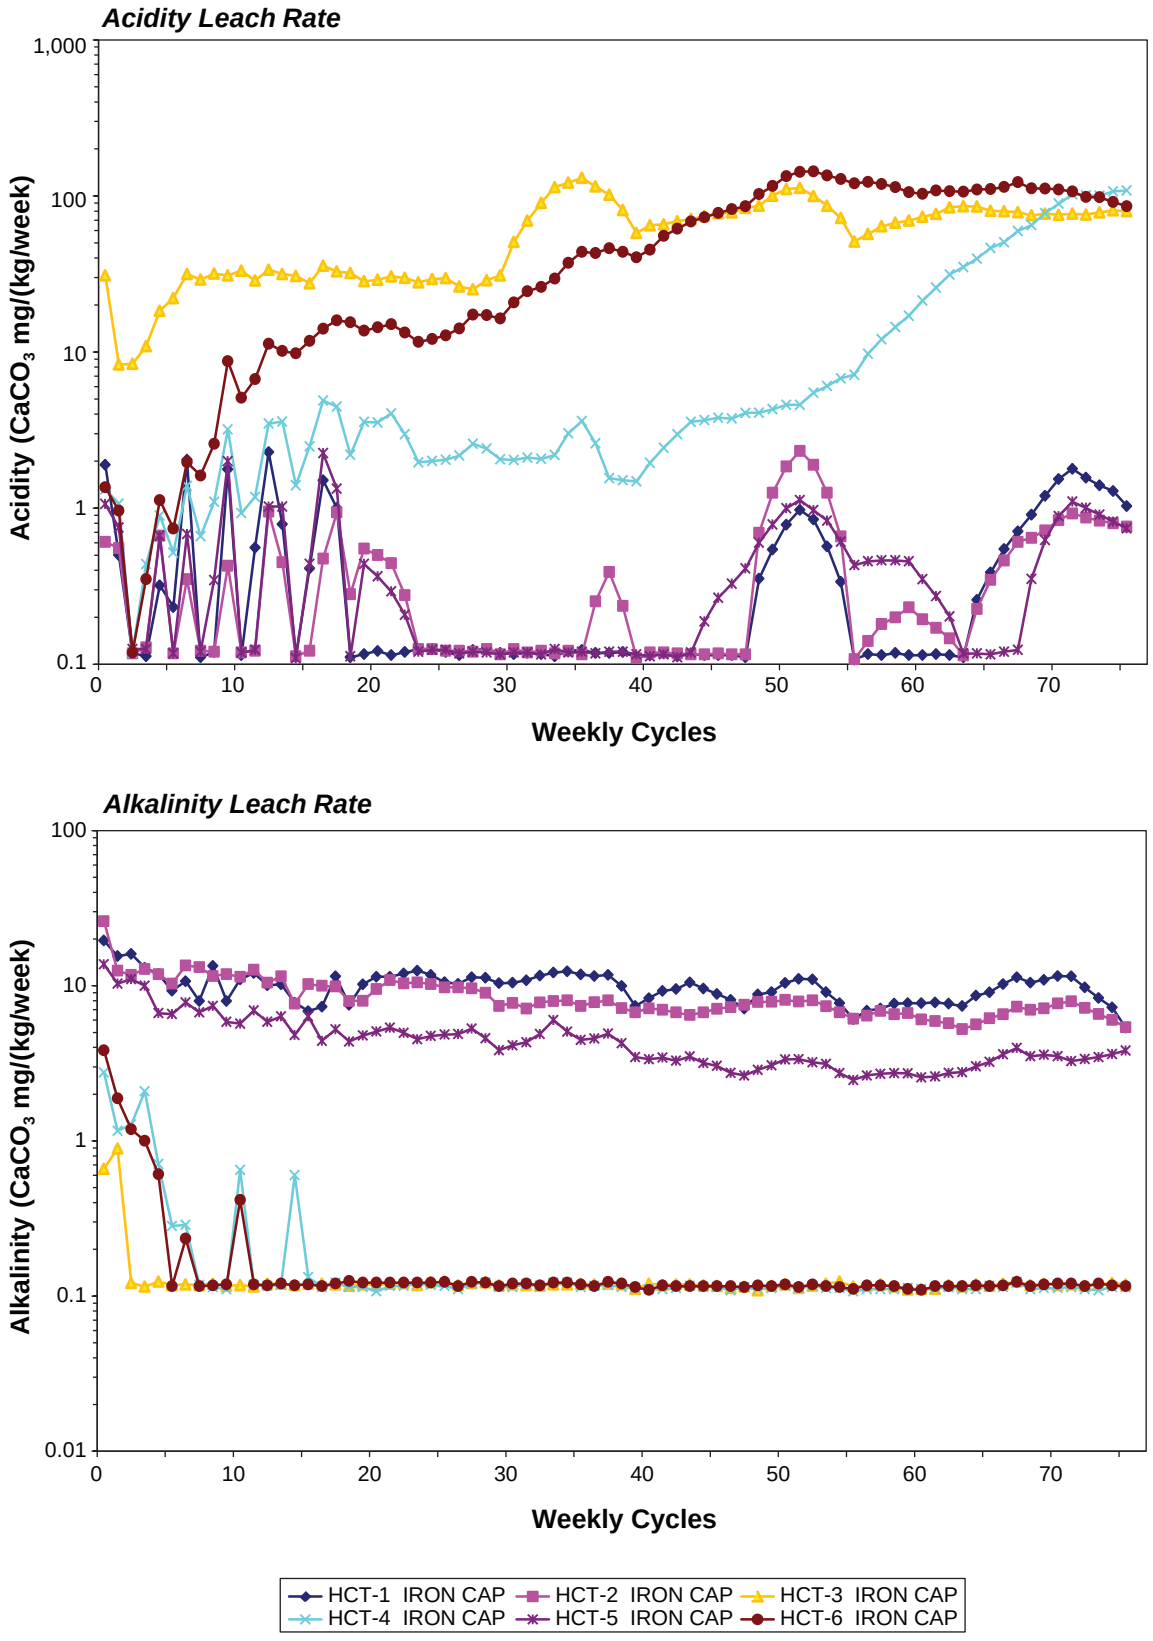
Iron leach rates increased over time in the three acidic humidity cells to 25 mg/kg/wk at week 75. Leach rates in the near-neutral humidity cells were variable over time (Figure 5.2-51).

Manganese leach rates were relatively stable over time in the near-neutral cells and decreased over time in the acidic cells. Leach rates ranged from 0.014 to 0.035 mg/kg/wk in the acidic humidity cells, and 0.03 to 0.1 mg/kg/wk in the near-neutral humidity cells (Figure 5.2-52).

Barium

Barium leach rates were variable over time ranging from 0.01 to 0.05 mg/kg/wk. Barium leach rates decreased after week 29 in HCT-3, but subsequently increased (Figure 5.2-52).

Trace Elements



Arsenic leach rates in HCT-3 and HCT-6 increased to between 0.0005 to 0.009 mg/kg/wk. Leach rates in HCT-4 increased after week 51 to a maximum of 0.02 mg/kg/wk. Leach rates in all other Iron Cap humidity cells decreased over time (Figure 5.2-53).

Beryllium concentrations were elevated in acidic humidity cells. Beryllium leach rates increased to approximately week 20 and leach rates in the last 10 weeks ranged from 0.0002 to 0.0025 mg/kg/wk. Beryllium concentrations in near-neutral humidity cells were frequently below detection (Figure 5.2-53).

Cadmium leach rates increased over time in the acidic humidity cells to between 0.002 and 0.013 mg/kg/wk and were relatively stable in the near-neutral cells ranging from 0.00001 to 0.0002 mg/kg/wk (Figure 5.2-54).

Chromium concentrations were frequently below detection limits, but leach rates increased after weeks 29 in HCT-3 and 6, and week 55 in HCT-4 (Figure 5.2-54).

Cobalt concentrations were elevated in acidic humidity cells. Leach rates in the acidic humidity cells ranged from 0.005 to 0.07 mg/kg/wk in week 37 and were orders of magnitude lower in the near-neutral humidity cells (Figure 5.2-55).

Copper leach rates increased over time in the acidic humidity cells and ranged from 0.3 to 3 mg/kg/wk in week 37 and were stable at 2.5 to 3.2 mg/kg/wk at week 75. Leach rates in the near-neutral humidity cells were stable over time and steady-state rates ranged from 0.01 to 0.002 mg/kg/wk (Figure 5.2-55).

Steady state fluoride leach rates in the acidic cells ranged from 0.4 to 8 mg/kg/wk. Fluoride leach rates in the near-neutral humidity cells decreased over time (Figure 5.2-56).

Lead leach rates increased over time in HCT-3, 4 and 6, but decreased after week 16 in HCT-3, after week 40 in HCT-6 and after week 66 in HCT-4 (Figure 5.2-56).

Mercury leach rates were elevated in HCT-3 and HCT-6 between weeks 33 and 67 and ranged from 0.000002 to 0.000004 mg/kg/wk. Leach rates decreased in the last 5 weeks. Mercury leach rates in HCT-4 increased after week 63 up to 0.000008 mg/kg/wk. Mercury concentrations were frequently below detection in all humidity cells and leach rates were highly variable (Figure 5.2-57).

Selenium concentrations decreased over time for all humidity cells and leach rates ranged from 0.00009 to 0.0008 mg/kg/wk at week 75 (Figure 5.2-57).

Nickel leach rates increased over time in the acidic HCT-3, 4, and 6 with leach rates ranging from 0.002 to 0.005 mg/kg/wk by week 75. Leach rates in the near-neutral humidity cells were frequently below detection (Figure 5.2-58).

Silver leach rates increased over time in the acidic HCT-3, 4, and 6 with leach rates ranging from 0.00009 to 0.00014 mg/kg/wk by week 75. Leach rates in the near-neutral humidity cells were frequently below detection (Figure 5.2-58).

Thallium leach rates were stable over time in all humidity cells and were elevated in acidic cells over near-neutral cells. The highest concentrations were observed in HCT-3 and 4 and steady state thallium leach rates were 0.0003 mg/kg/wk in HCT-3 and decreased to 0.00003 mg/kg/wk in HCT-4 (Figure 5.2-59).

Zinc leach rates increased over time in the acidic cells to between 0.11 to a maximum of 2.8 mg/kg/wk at week 53, and were highly variable in the near-neutral cells (Figure 5.2-59).

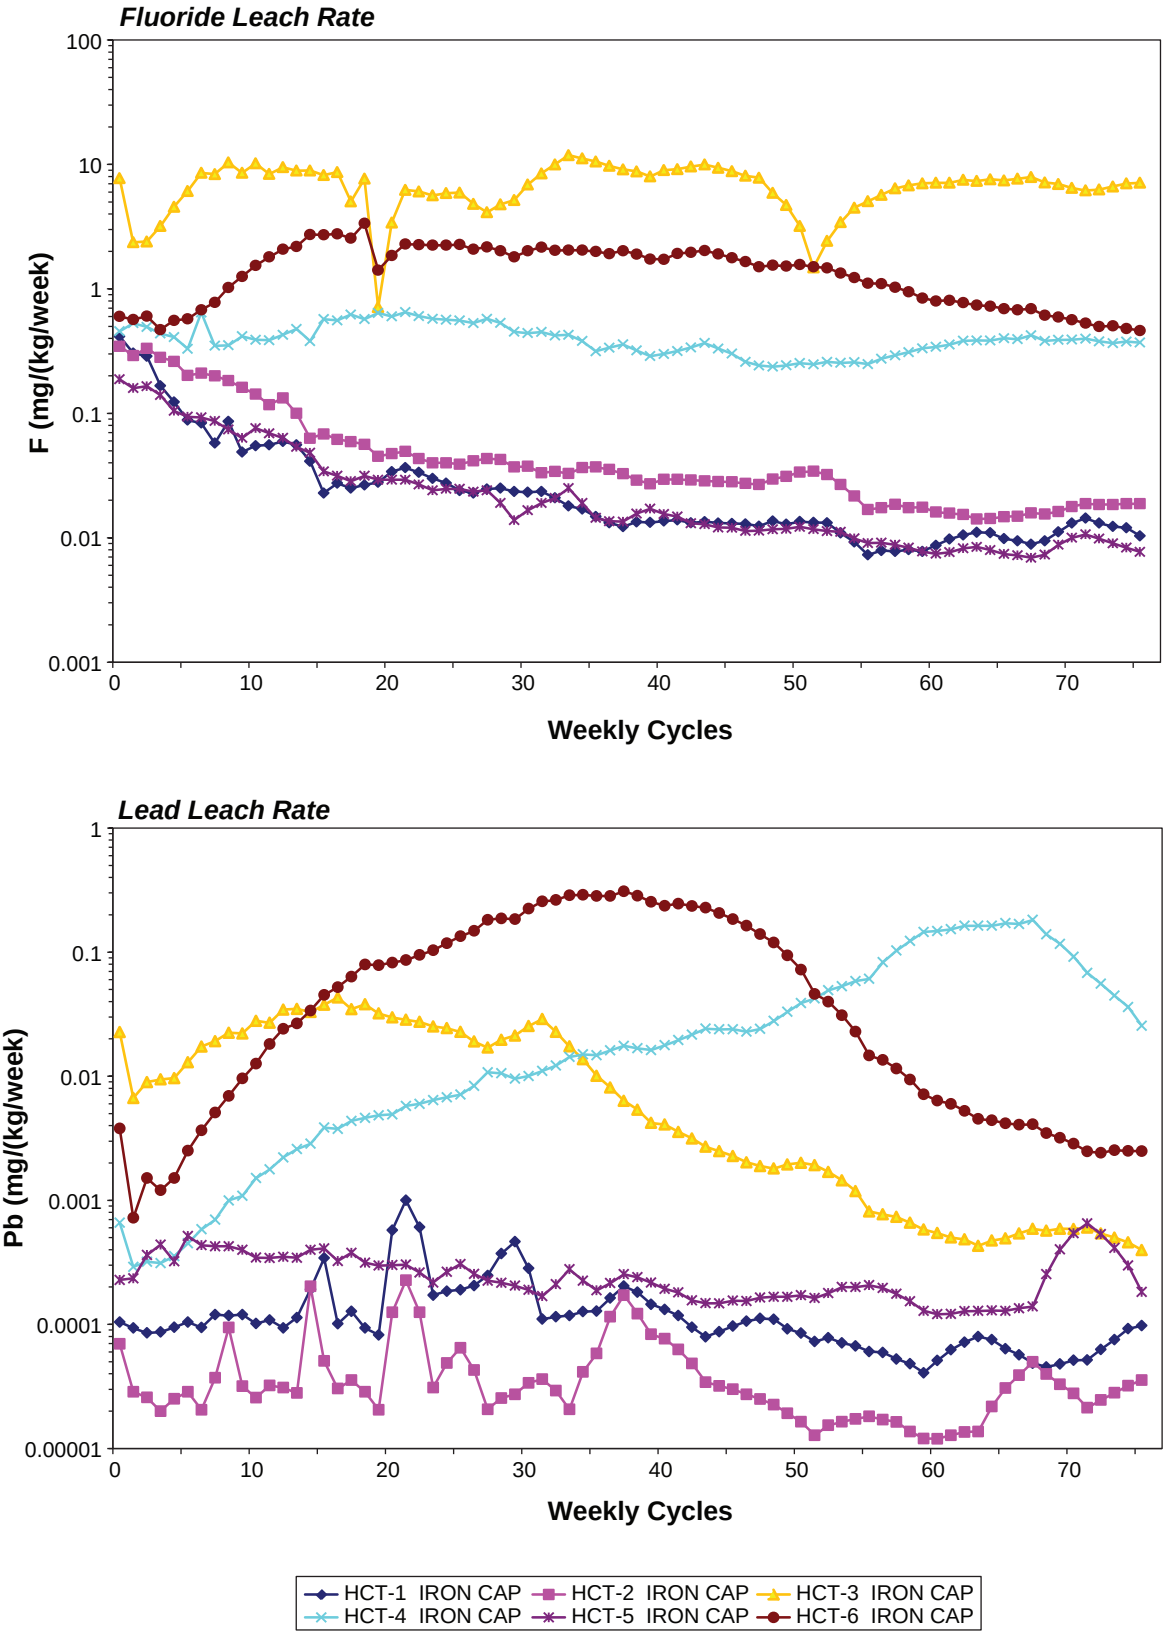

Table 5.2-5 summarizes the parameters with elevated concentrations by model code under acidic and neutral drainage conditions in order to inform treatment design.

Table 5.2-5. Iron Cap Deposit Acidic and Neutral Leachate from Humidity Cells

Model Code	Acidic Drainage	Neutral Drainage
Iron Cap	Sulphate, Aluminum, Arsenic, Cadmium, Chromium, Cobalt, Copper, Fluoride, Iron, Lead, Nickel, Selenium, Silver, Thallium, Zinc	Aluminum, Cadmium, Copper, Selenium, Thallium

Elements associated with the Neutralization Potential

After an initial decrease, calcium leach rates were relatively stable in all humidity cells and ranged from 1.8 to 13 mg/kg/wk, with the exception of HCT-6 in which the calcium leach rates decreased after week 53 to a mimunim of 2.7 mg/kg/wk. Magnesium leach rates decreased over time for all humidity cells, with the exception of HCT-1 which remained stable at around 0.3 mg/kg/wk (Figure 5.2-60).

5.2.1.3 Post-test Static Test Results

As part of the humidity cells closedown procedure, ABA static tests have been performed on the samples solid phase. Appendix 5.2-7 presents the post-humidity cells solid-phase static tests results for the KSM Project.

5.2.1.4 Depletion Times and Onset of Acid Rock Drainage

The rates of depletion of sulphide, bulk Sobek NP, and carbonate NP were calculated and used to estimate the time to the onset of ARD. Table 5.2-6 presents a summary of these data by ABA block model code.

The onset to ARD for acidic humidity cells or humidity cells with no available NP is 0 years, indicating that ARD is predicted to be immediate or within weeks for waste rock represented by these humidity cells. ARD from waste rock from the Kerr Deposit is predicted to occur within a range of immediate to 92 years, with an end to sulphide depletion occurring three to 263 years following ARD onset. ARD from waste rock from the Sulphurets Deposit is predicted to occur within a range of immediate to 147 years (never if based on Bulk NP), with an end to sulphide depletion occurring eight to 296 years subsequently. ARD from waste rock from the Mitchell Deposit upper panel is predicted to occur within a range of two to 268 years, with an end to sulphide depletion occurring two to 629 years following ARD onset. ARD from waste rock from the Mitchell Deposit lower panel is predicted to occur within a range of immediate to 307 years (never if based on Bulk NP), with an end to sulphide depletion occurring nine to 469 years subsequently. ARD from waste rock from the Iron Cap deposit is predicted to occur within the range of immediate to 233 years, with an end to sulphide depletion occurring from 50 to 27, 257 years subsequently. It should be noted that ARD onset predictions are based on the assumption that stable leach rates will persist; however, little long-term data exists to assess this assumption (Price 2009). Stable rates can persist within a factor of two for at least five years, but these ARD onset predictions should be updated and assessed by ongoing kinetic testing and monitoring (Day 1994). A reduction in leach rates over the long-term is expected, and will increase the time to predicted ARD onset.

The results indicated considerable disagreement in predictions of ARD onset based on the source of NP (measured bulk Sobek NP or calculated carbonate NP). Notably, ARD was never predicted to occur for some cells of Sulphurets (UP Hazelton, Lowe Au zone) and Mitchell (Monzonite, LP Hazelton) based on depletion of bulk NP, but was predicted to occur within 43 to 183 years based on depletion of carbonate NP. This discrepancy in onset to ARD time also predicted that two humidity cells with adjusted SNPR > 2 (Sulphurets UP Hazelton and Mitchell upper panel Monzonite) would become acidic in approximately 40 years based on the depletion of carbonate NP. Section 4 has a detailed description of the methods used to calculated depletion times and ARD onset.

5.2.2 Sub-Aerial Drip Columns

This section presents the results of static tests and kinetics tests performed on four laboratory sub-aerial drip columns constructed using drill core samples of the same model codes as were used for KSM field leach barrels 1 to 4. The laboratory column material represents M UP Hazelton, M LP Hazelton, and M Monzonite model codes.

5.2.2.1 Pre-Test Static Test Results

The full static test dataset can be found in Appendix 5.2-8. Detailed analytical mineralogy and petrographic studies for waste rock can be found in Appendix 5.1-2 and 5.1-3, respectively, and are referred to elsewhere in this report (Section 5.1).

The statistical summary of the solid phase elemental analysis results is presented in Section 5.2.3.1.

Paste pH

Figure 5.2-61 presents the plots of the paste pH values of the sub-aerial drip column samples in relation to the statistical distribution of the paste pH values determined for all waste rock samples by model code. The results show that all the sub-aerial drip columns samples are within the pH interquartile range for their model code.

Sulphur Species

Figure 5.2-62 presents the plots of the total-sulphur values of the sub-aerial drip column samples in relation to the statistical distribution of the total-sulphur values determined for all waste rock samples by model code. The results show that all the sub-aerial drip column samples are within the total-sulphur interquartile range for their model code.

Figure 5.2-63 presents the plots of the sulphide-sulphur values of the sub-aerial drip column samples in relation to the statistical distribution of the sulphide-sulphur values determined for all waste rock samples by model code. The results show that all the sub-aerial drip column samples are within the sulphide-sulphur interquartile range for their model code.

Neutralization Potential

Figure 5.2-64 presents the plots of the NP values of the sub-aerial drip column samples in relation to the statistical distribution of the NP values determined for all waste rock samples by model code. The results show that all the sub-aerial drip columns samples are within the NP range for their model code.

Sulphide Net Potential Ratio

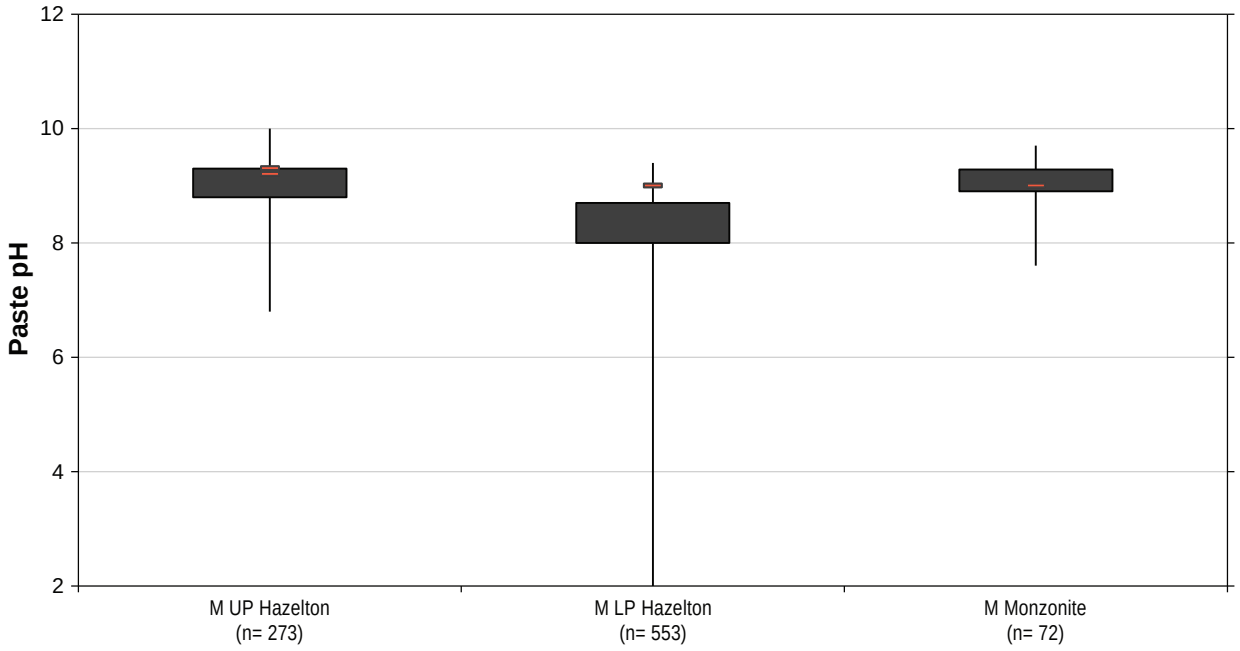

Figure 5.2-65 presents the plots of the adjusted SNPR values of the sub-aerial drip column samples in relation to the statistical distribution of the adjusted SNPR values determined for all waste rock samples by model code. The results show that all the sub-aerial drip column samples are within the adjusted SNPR interquartile range for their model code.

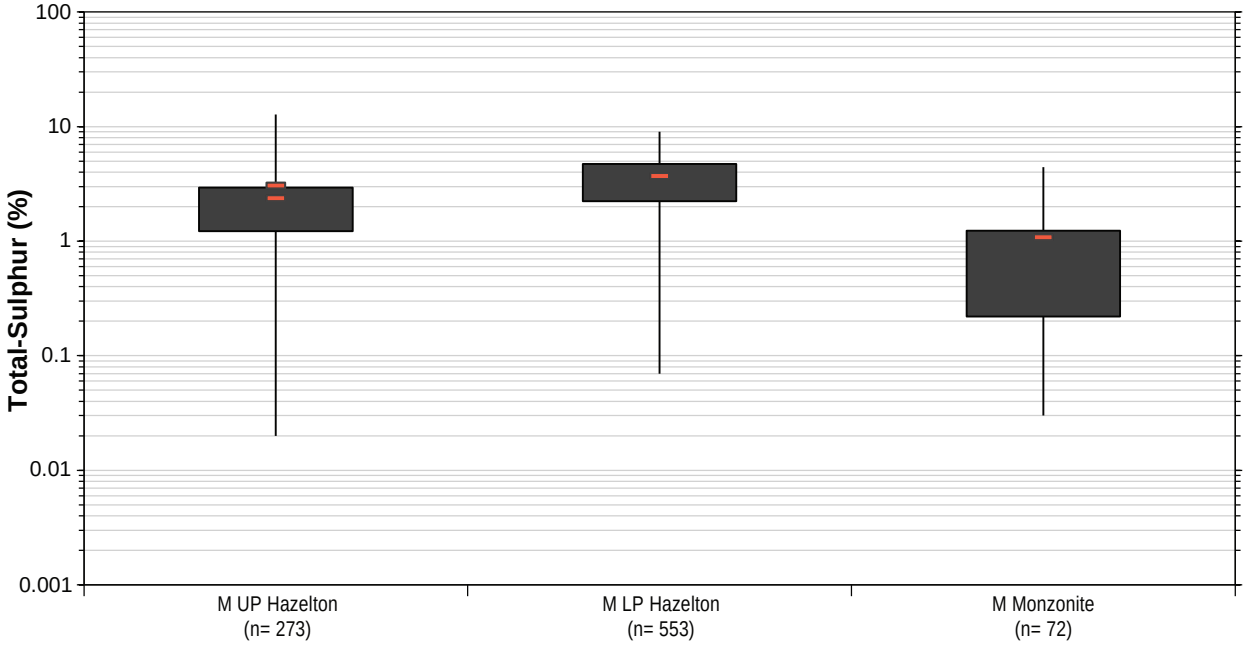
5.2.2.2 Kinetic Test Results

The following discussion presents the results for the leachate analyses from the sub-aerial laboratory drip columns for the Mitchell Deposit for:

- Indicators of acid generation (pH, sulphate, and alkalinity);
- Elements that contribute to acidity (aluminum, iron, and manganese);
- Trace elements with elevated concentrations in the last 10 weekly cycles relative to water quality guidelines. Identification of these elements can be used to inform treatment design decisions, including treatment at the proposed Water Treatment Plant (WTP), and water quality modelling; and
- Calcium and magnesium which commonly occur in carbonate mineral phases and are associated with the neutralization potential.

The sub-aerial drip column data are supplemental to the humidity cell data and primarily serve as a comparison. Mitchell Deposit waste rock is expected to dominate the waste rock chemistry at the Project, therefore, only Mitchell Deposit material was selected for these kinetic tests. The complete data set for the sub-aerial laboratory drip columns leachate concentrations is presented in Appendix 5.2-9. Leachate water was recirculated during the kinetic tests and therefore leach rates could not be accurately calculated or evaluated. The following ABA block model codes were represented: a composite of UP Hazelton and Monzonite (Columns 1, 2, and 3) and a composite of UP Hazelton and LP Hazelton (Column 4).



Note: 25th to 75th percentile is represented by the shaded box. The red bars indicate individual humidity cells.

Statistical Summary - Adjusted Sulphide Net Potential Ratio by Model Code for Sub-Aerial Drip Columns

Figure 5.2-65

Rescan™ Engineers & Scientists

These data represent four sub-aerial laboratory drip columns, constructed using waste rock from the Mitchell Deposit that was operated for 107 weeks. Data was collected for the first two weeks, and from week 30 to week 107.

pH, Sulphate, and Alkalinity

The pH remained near neutral at approximately pH 8 for 107 weeks in all four drip columns. Steady-state sulphate concentrations ranged from 30 mg/L in Column 1 to 80 mg/kg/wk in Column 4. The stable pH indicated that any acid produced during sulphide oxidation was effectively neutralized. Weekly alkalinity observations showed some variability in Column 1, but steady alkalinity was produced in Columns 2 to 4 at approximately 36 mg $CaCO_3$/L (Figure 5.2-66).

Elements that Contribute to Acidity

Aluminum concentrations were generally stable with concentrations approximately 0.03 mg/L in Columns 1 and 2 and 0.01 mg/L in Columns 3 and 4. Iron concentrations were below the detection limit in all columns for 107 weeks. Manganese concentrations ranged from 0.08 mg/L in Column 1 to 0.4 mg/L in Column 3 and were stable over time (Figure 5.2-67).

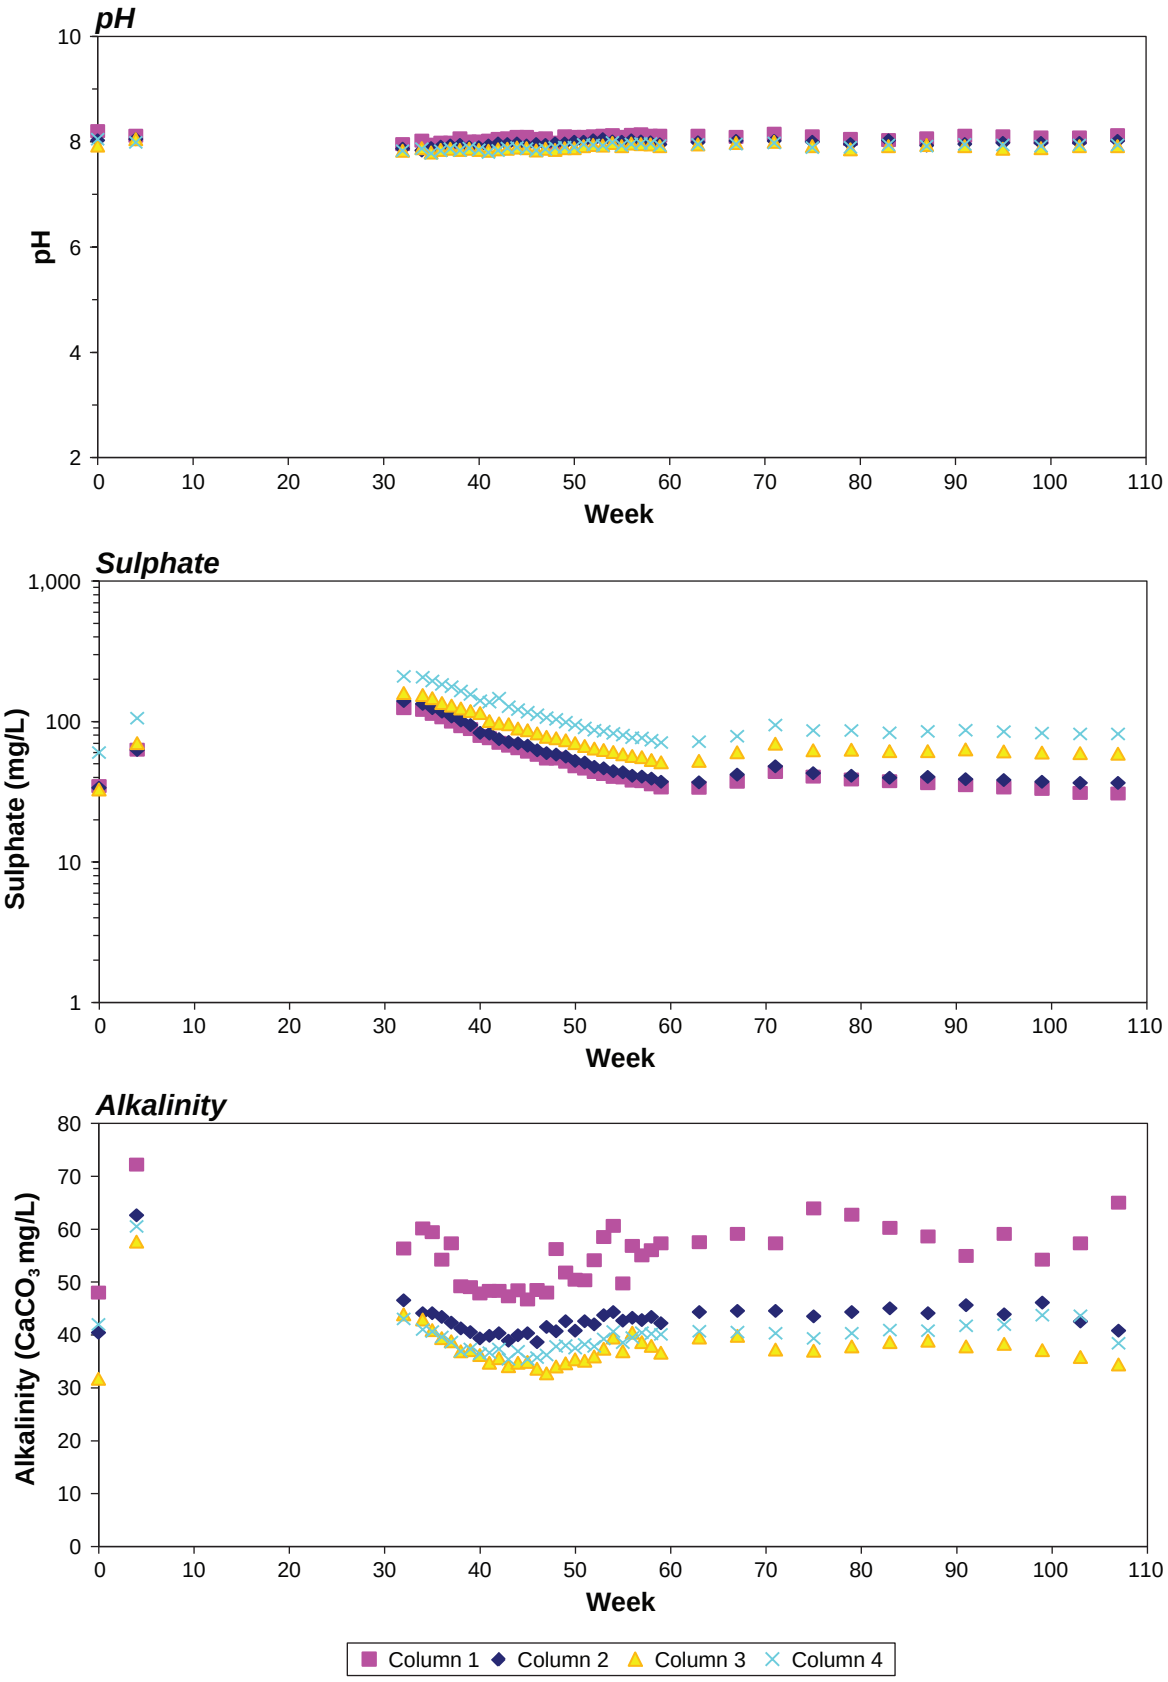
Trace Elements

Stable cadmium concentrations were 0.00008 mg/L, 0.0001 mg/L, and 0.0005 mg/L in Columns 2 to 4, respectively (Figure 5.2-68). Cadmium concentrations in Column 1 were always below the detection limit.

Fluoride concentrations were similar in Columns 1 and 2 and were approximately 0.9 mg/L. Concentrations in Columns 3 and 4 decreased over time to final values of 0.07 mg/L (Figure 5.2-68).

Selenium concentrations decreased over time in all four columns to final concentrations ranging from 0.003 mg/L in Column 1 to 0.01 mg/L in Column 3 (Figure 5.2-68).

Elements Associated with the Neutralization Potential



Steady state calcium concentrations ranged from 24 mg/L in Column 1 to 42 mg/L in Column 4. Steady state magnesium concentrations ranged from 2 mg/L in Column 2 to 5 mg/L in Column 1. Calcium and magnesium concentrations were stable from week 60 to week 107 (Figure 5.2-69).

5.2.3 Field Leach Barrels

This section presents the results of pre-kinetic static tests performed on 12 field leach barrels and the results of kinetic tests performed on 18 field leach barrels constructed at the KSM Project exploration camp near Sulphurets Creek to assess the ML/ARD properties of potential waste and pit wall rock material in the proposed KSM Project mine area. The Kerr Deposit is represented by Barrel 9, the Sulphurets Deposit is represented by barrels 10, 11, and 14, the Mitchell Deposit upper panel is represented by barrels 1 to 3, 8, 12, 15, and 16, and the Mitchell Deposit lower panel is represented by barrels 4 to 7, 13, and 17. The Iron Cap Deposit is not represented by any field leach barrels; however, the design change to block caving has greatly reduced the volume of waste rock proposed to be produced from the Iron Cap Deposit. Furthermore, the Mitchell Deposit waste rock field leach data are a reasonable approximation of the Iron Cap waste rock.

5.2.3.1 Pre-test Static Test Results

Static tests results are only available for 12 drill core samples. The full static test dataset can be found in Appendix 5.2-10. Detailed analytical mineralogy and petrographic studies for waste rock can be found in Appendix 5.1-2 and 5.1-3, respectively, and are referred to elsewhere in report (Section 5.1).

Paste pH

Figure 5.2-70 presents the paste pH of the field leach barrel samples in relation to the statistical distribution of the pH values determined for all waste rock samples by model code. The table shows that the majority of the field leach barrel samples are within the pH interquartile range for their model code.

Sulphur Species

Figure 5.2-71 presents the total-sulphur content of the field leach barrel samples in relation to the statistical distribution of the total-sulphur values determined for all waste rock samples by model code. The results show that the majority of the field leach barrel samples are within the total-sulphur interquartile range for their model code. All leach barrel samples exhibited total-sulphur values within the minimum and maximum range.

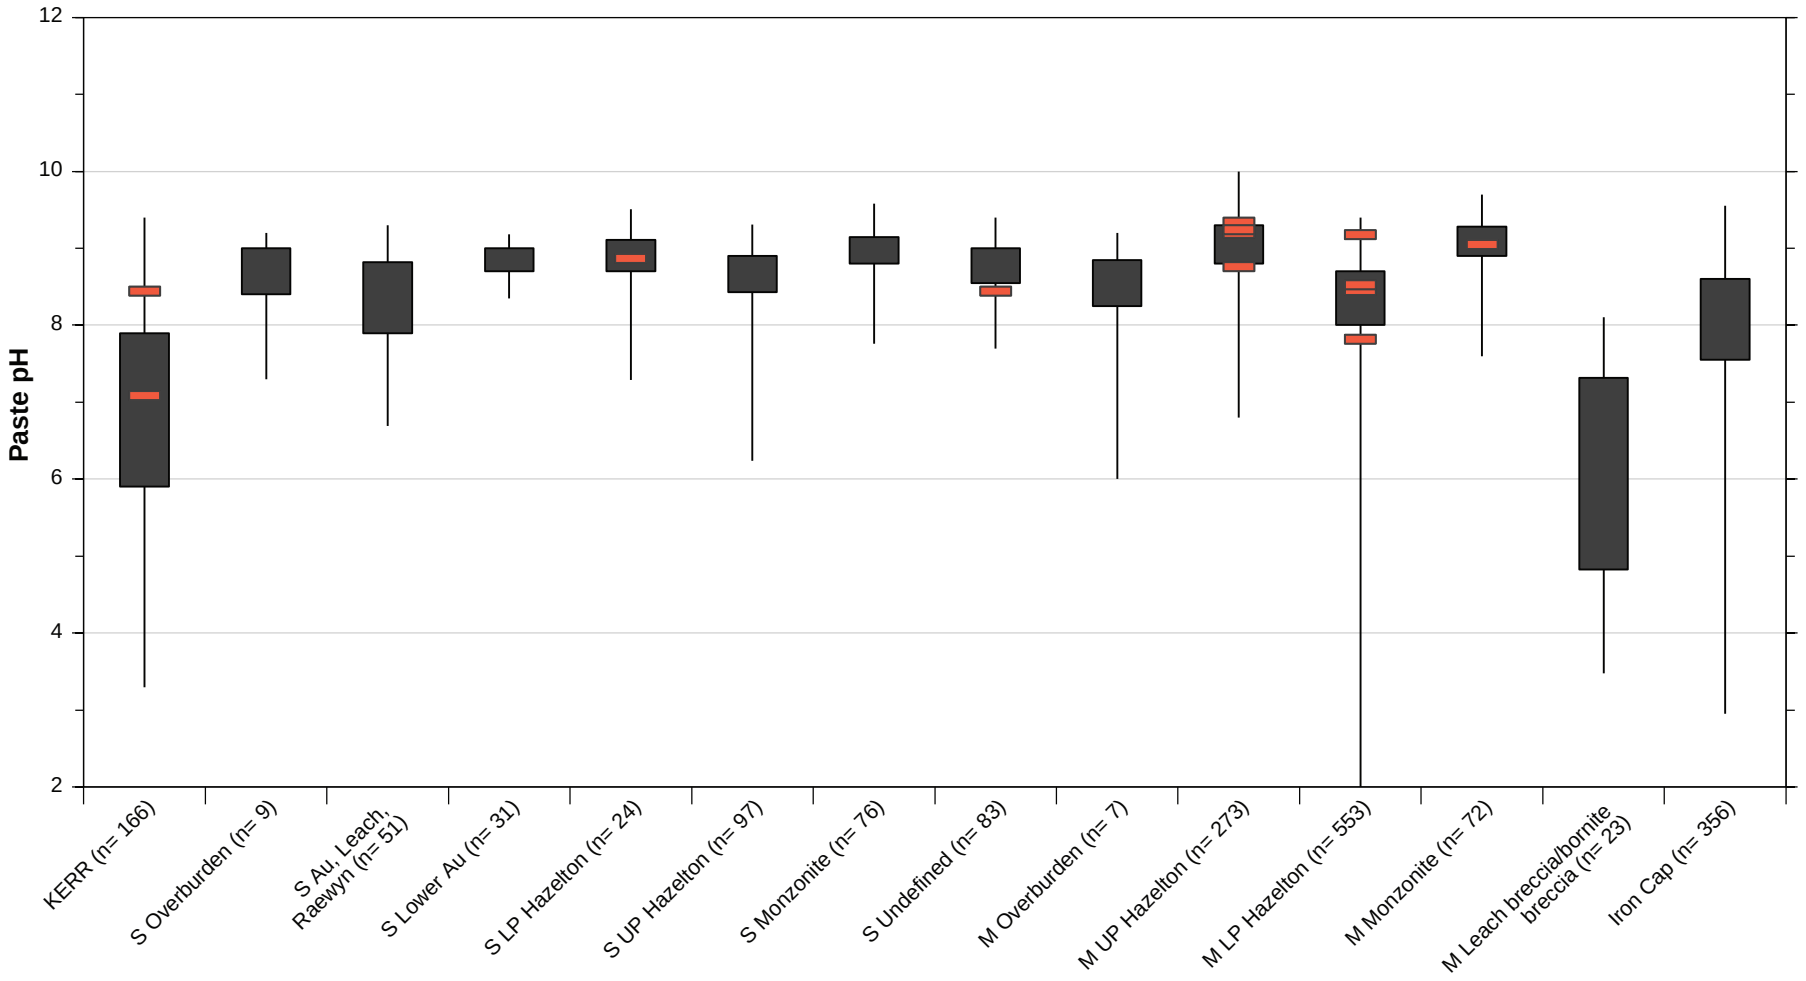
Figure 5.2-72 presents the sulphide-sulphur content of the field leach barrel samples in relation to the statistical distribution of the sulphide-sulphur values determined for all waste rock samples by model code. The results show that the majority of the field leach barrel samples are within the sulphide-sulphur interquartile range for their model code. All leach barrels samples exhibited sulphide-sulphur values within the minimum and maximum range.

Neutralization Potential

Figure 5.2-73 presents the NP values of the field leach barrel samples in relation to the statistical distribution of the NP values determined for all waste rock samples by model code. The results show that the majority of the field leach barrel samples are within the NP interquartile range for their model code.

Sulphide Net Potential Ratio

Figure 5.2-74 presents the adjusted SNPR values of the field leach barrel samples in relation to the statistical distribution of the adjusted SNPR values determined for all waste rock samples by model code. The results show that the majority of the field leach barrel samples are within the adjusted SNPR interquartile range for their model code.



Whole Rock and Solid-phase Analysis

The multi-element concentrations in field leach barrel samples from the KSM Project were measured by ICP-MS analysis after strong four-acid digestion and by XRF whole-rock analysis. The results are found in Appendix 5.2-10.

Most of the field leach barrel samples were comprised of oxide-equivalents of SiO_2 and Al_2O_3, which is consistent with the dominant presence of quartz, feldspar minerals, and other aluminosilicate minerals in KSM rocks. Also consistent with general mineralogy, there were lesser but still significant amounts of K_2O, Fe_2O_3, CaO, MgO, and Na_2O.

In order to assess which solid-phase elements are elevated, they were compared to crustal abundances for the rock types basalt, and shales (Price 1997). This comparison was used as a preliminary screening tool to indicate which solid-phase elements may also be elevated in site mine drainage waters.

Table 5.2-7 presents the results for element median values exceeding three times the crustal abundance. It shows that the elements frequently exceeding three times basalt crustal abundance were silver, arsenic, bismuth, cesium, copper, potassium, molybdenum, lead, rubidium, sulphur, antimony, selenium, thallium and tungsten. Elements frequently exceeding three times the shale crustal abundance were silver, copper, molybdenum, sulphur, and selenium. Elements frequently exceeding three times high-calcium granite crustal abundance were silver, arsenic, copper, molybdenum, sulphur, antimony, selenium, and tungsten.

Note: 25th to 75th percentile is represented by the shaded box. The red bars indicate individual humidity cells.

Statistical Summary for Field Leach Barrels - Adjusted Sulphide Net Potential Ratio Values

Figure 5.2-74

Rescan™ Engineers & Scientists

5.2.3.2 Kinetic Test Results

The following discussion presents the results of the analyses of leachate from the field leach barrels for:

- Indicators of acid generation (pH, sulphate, acidity, and alkalinity);
- Elements that contribute to acidity (aluminum, iron, and manganese);
- Barium which is most commonly associated with barite ($BaSO_4$), a highly insoluble mineral;
- Trace elements with elevated concentrations in all samples relative to water quality guidelines. Identification of these elements can be used to inform treatment design decisions, including treatment at the proposed Water Treatment Plant (WTP), and water quality modelling; and
- Calcium and magnesium which commonly occur in carbonate mineral phases and are associated with the neutralization potential.

Total element concentrations for each sample date have been normalized to the height of rock in the barrel (in centimetres) and the volume of water in the collection pail (in litres) and this normalized data is presented graphically for selected elements with elevated concentrations. The complete data set for field barrel leachate concentrations is presented in Appendix 5.2-11. Normalized data for additional selected parameters are presented graphically in Appendix 5.2-12.

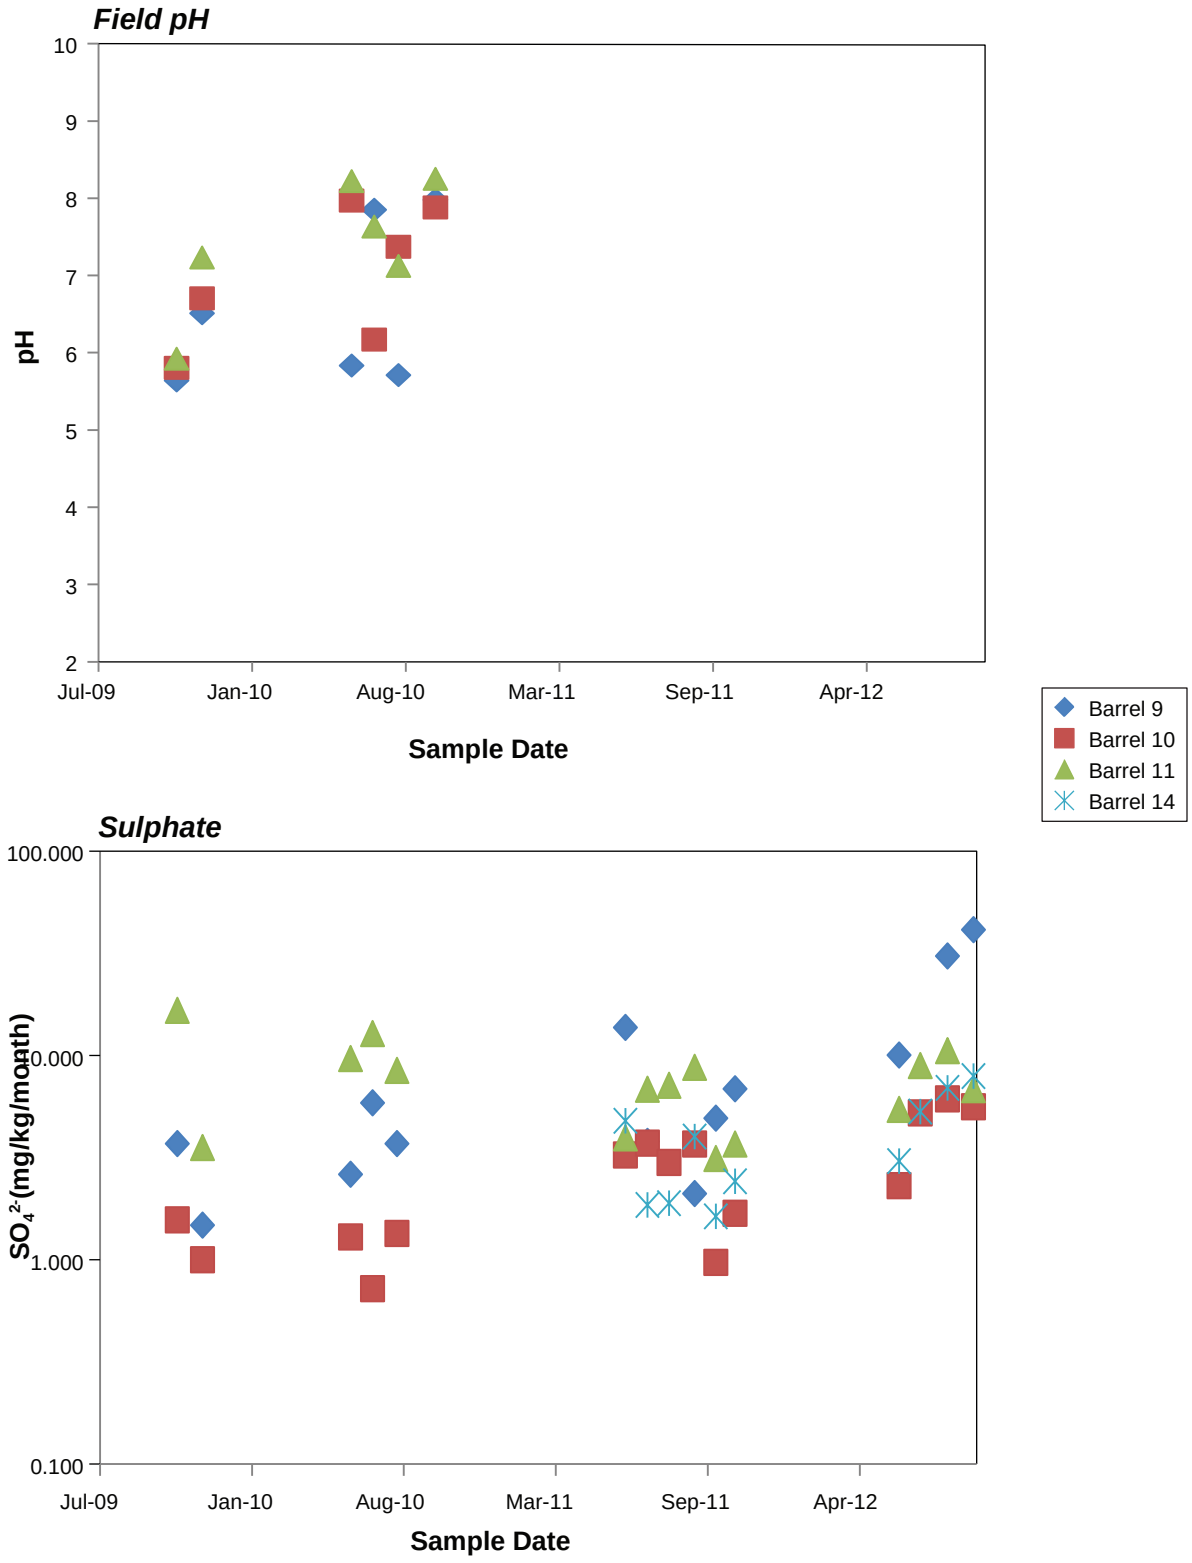
Kerr and Sulphurets Deposits

pH, Sulphate, Acidity, and Alkalinity

The pH of leachate from all Kerr and Sulphurets field barrels were acidic at one or more sampling times. Barrel 9 (Kerr) had highly variable pH between 5.8 and 8.3 for the first 20 months, but decreased steadily to pH 5.2 in the last 5 months. The pH of leachate from Barrels 10, 11, and 14 (Sulphurets) was variable in the first 2 years of sampling, but generally stabilized between pH 7 and 8 in 2011 (Figure 5.2-75).

Sulphate concentrations were generally stable in Barrels 9 (Kerr), 10, and 14 (Sulphurets). The normalized sulphate decreased from 100 mg/cm to 14 mg/cm in Barrel 11 over 2 years, indicating flushing of surface precipitates (Figure 5.2-75).

Acidity was highly variable in Barrel 10, but tended to increase over time in Barrels 9, 11, and 14 (Figure 5.2-76).



Alkalinity was typically lower and more variable in Barrel 9 compared to the other three barrels. Alkalinity in Barrel 11 decreased through the summer, and had a higher value at the beginning of the subsequent year. Alkalinity in Barrel 11 and 14 was less variable (Figure 5.2-76).

Nutrients and Total Organic Carbon

Total nitrogen and total phosphate (as P) concentrations were low and frequently below the detection limit. Total organic carbon decreased over time in all Kerr and Sulphurets field barrels (Figure 5.2-77).

Elements that Contribute to Acidity

Total aluminum in Barrel 9 leachate showed a seasonal trend, increasing throughout the summer, with a lower concentration at the beginning of the following year. Total aluminum in the three Sulphurets barrels leachates decreased over time. In general, dissolved aluminum concentrations followed the same trend as total aluminum (Figure 5.2-78).

Total and Dissolved Aluminum, Kerr and Sulphurets Deposits Field Leach Barrels

Figure 5.2-78

Rescan™ Engineers & Scientists

Total and dissolved iron concentrations decreased over time and were frequently below detection in all Kerr and Sulphurets field barrel leachates (Figure 5.2-79).

Manganese concentrations were elevated in Barrel 9 (Kerr) leachate. Manganese concentrations increased over time in Barrel 9 leachate. Manganese in Barrel 10 leachate exhibited a strong seasonal trend with increases over the winter, and decreased concentrations due to flushing through the summer. Manganese in Barrels 11 and 14 leachates decreased over time (Figure 5.2-80).

Barium

Barium concentrations were generally stable in leachates from all Kerr and Sulphurets field barrels, with some variability in Barrel 9 (Figure 5.2-80).

Trace Elements

Cadmium concentrations in Barrel 9 leachate increased over time. Cadmium in leachate from Barrels 10, 11, and 14 was generally stable and frequently below the detection limit (Figure 5.2-81).

Cobalt concentrations were elevated in Barrel 9 leachate. Cobalt in Barrel 9 leachate increased over time. Cobalt in Barrel 10 leachate exhibited a seasonal trend, decreasing during the summer, but building up during the winter. Cobalt in Barrels 11 and 14 leachates decreased over time (Figure 5.2-81).

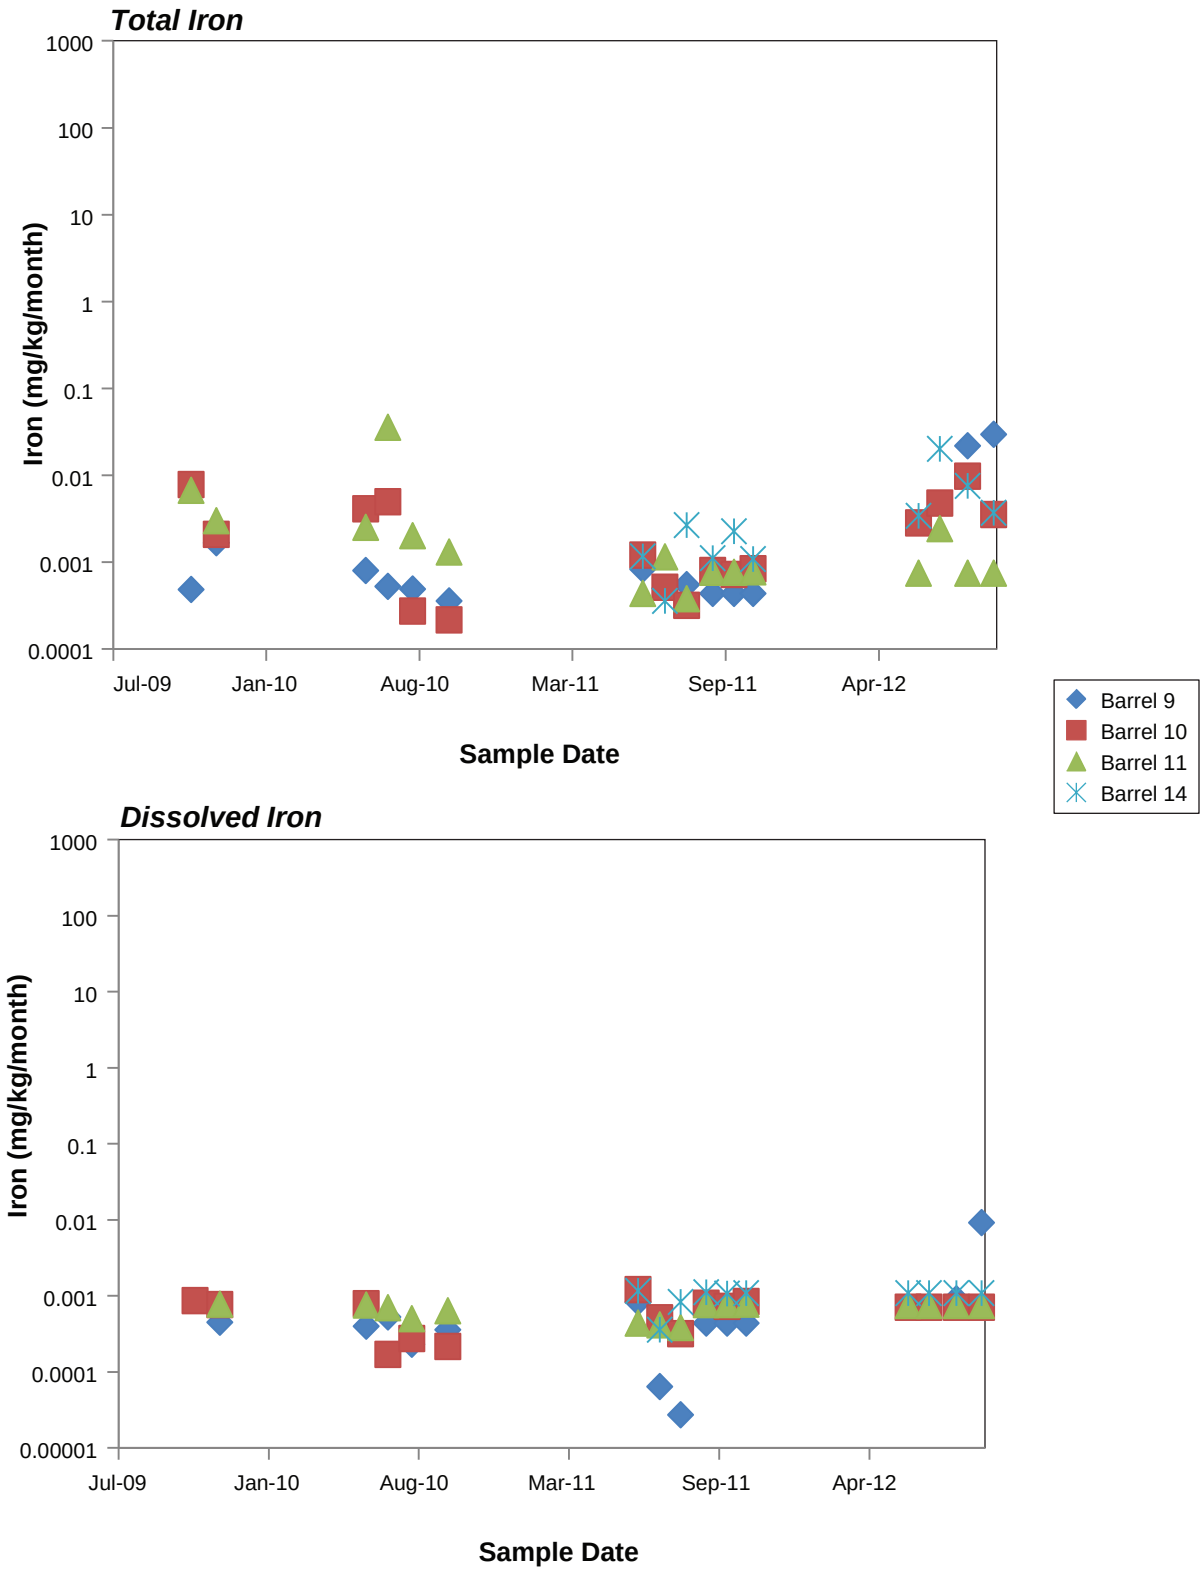
Copper in Barrel 9 leachate increased over time. Copper concentrations in Barrels 10, 11, and 14 decreased over time, and indicated a flushing of surface precipitates in the first sample of the year (Figure 5.2-82).

Molybdenum concentrations were elevated in near-neutral field barrels over the acidic Barrel 9. Molybdenum concentrations were generally stable over time in leachate from all barrels (Figure 5.2-82).

Selenium concentrations in Barrel 9 were variable. Selenium in barrels 10, 11, and 14 decreased over time (Figure 5.2-83).

Zinc concentrations were increased in 2011 over 2010 concentrations and were relatively stable in Barrels 9, 10, and 11 between 0.1 and 0.4 mg/cm. Zinc in Barrel 14 leachate was frequently below the detection limit (Figure 5.2-83).

Elements Associated with the Neutralization Potential



Calcium concentrations in leachate from Barrel 9 increased over time. Calcium in leachate from Barrel 10 decreased in 2011 but were increased and relatively stable in 2011. Calcium in Barrels 11 and 14 were generally stable over time (Figure 5.2-84).

Magnesium concentrations were generally stable over time in leachate from all Kerr and Sulphurets barrels, with some variability in Barrel 9 (Figure 5.2-84).

Mitchell Deposit

pH, Sulphate, Acidity, and Alkalinity

The pH of the leachate of upper panel Barrels 1, 2, 3, 12, 15 and all lower panel barrels were acidic at least once. The pH of the upper panel barrels was generally stable in the last year between pH 6 and 8. The pH of leachate from Barrels 4 to 7 was typically near-neutral in 2011. Barrels 13 and 17 containing weathered intensely altered outcrop had pH values less than 3 from the initial construction in June 2011 (Figures 5.2-85, 5.2-86).

Figure 5.2-86

Rescan™ Engineers & Scientists

Sulphate concentrations in leachate from upper panel barrels were generally stable over time ranging from 5 to 60 mg/cm in 2011. Sulphate concentrations in Barrel 4 (which contained upper and lower panel material) leachates were one to two orders of magnitude less than the other lower panel barrels. Sulphate in leachate from Barrels 5, 13, and 17 increased over time (Figures 5.2-85, 5.2-86).

Acidity and alkalinity were generally stable in leachate from all Mitchell Deposit barrels except lower panel Barrels 13 and 17 where acidity was two to three orders of magnitude higher and increased over time and alkalinity was below detection (Figures 5.2-87, 5.2-88).

Nutrients and Total Organic Carbon

Total nitrogen was comparable between upper and lower panel barrels. Total phosphate was comparable between upper and lower panel barrel leachates, with the exception of high total phosphate in acidic Barrels 13 and 17. Total organic carbon decreased over time in leachates from lower panel barrels and upper panel Barrel 12, but was generally stable in the remaining upper panel barrels (Figures 5.2-89, 5.2-90).

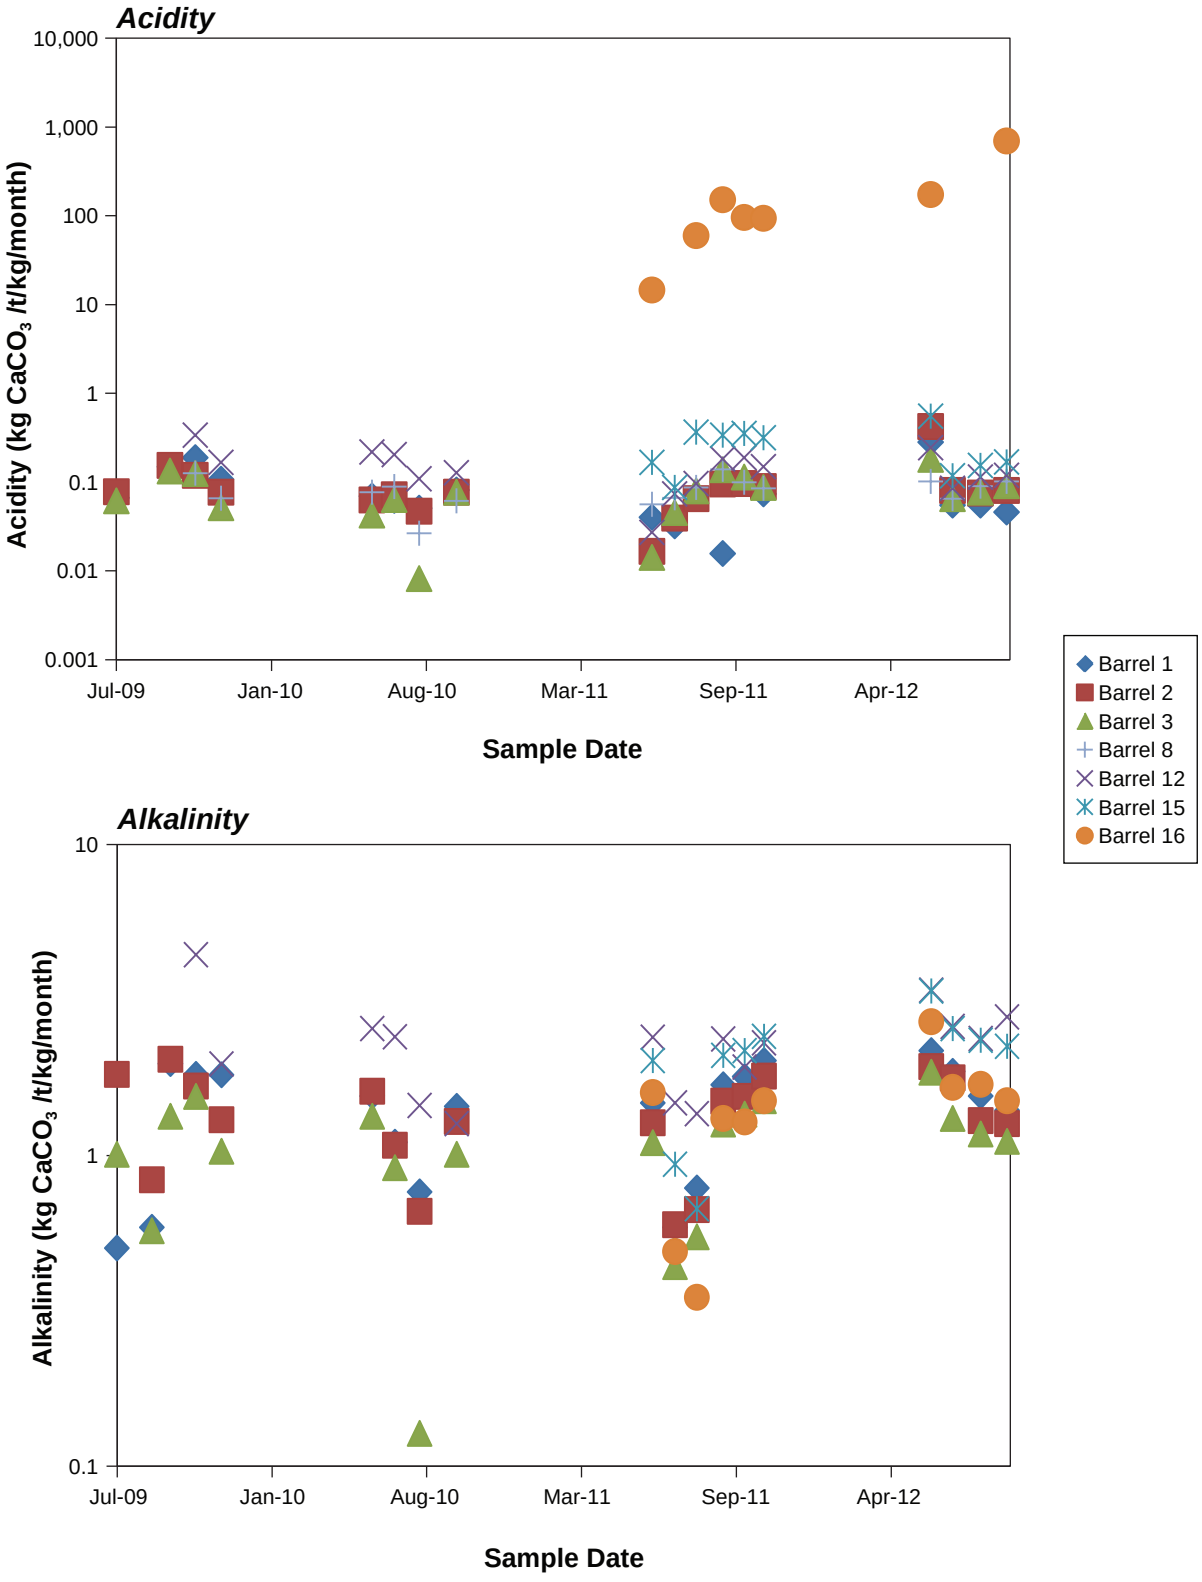
Elements that Contribute to Acidity

Total aluminum was generally stable in upper panel barrel leachates. Increased concentrations in the summer in lower panel Barrel 5 leachate in 2009 and 2010 were noted, but concentrations were low and stable in 2011. Total aluminum in the acidic Barrels 13 and 17 leachates were three to four orders of magnitude higher than in the other field barrels. Dissolved aluminum was frequently below the detection limit in all field barrel leachates, except the acidic Barrels 13 and 17 (Figures 5.2-91, 5.2-92).

Total and dissolved iron was frequently below the detection limit in all field barrel leachates except the acidic Barrels 13 and 17, where concentrations increased over time in 2011 and ranged from 12 to 770 mg/L (Figures 5.2-93, 5.2-94).

Manganese concentrations generally decreased over time in all upper panel and lower barrel leachates. A steady decrease in manganese concentrations in 2011 from June to October was evident. Manganese in the acidic Barrels 13 and 17 was two orders of magnitude greater than other lower panel barrels (Figures 5.2-95, 5.2-96).

Barium



Barium was generally stable around 0.01 mg/cm in leachate from upper panel barrels, but showed a high degree of variability in lower panel barrels (Figures 5.2-95, 5.2-96).

Trace Elements

Chloride and fluoride were elevated in leachate from the acidic Barrels 13 and 17 only. Concentrations of chloride in leachate from these two barrels increased over time, while fluoride concentrations increased from June to the beginning of September in 2011 before decreasing to the end of October (Figures 5.2-97).

Antimony concentrations were generally stable and comparable across upper and lower panel barrel leachates (Figure 5.2-98).

Arsenic concentrations were elevated in leachates from upper panel Barrel 16 and lower panel Barrels 7, 13, and 17. Arsenic concentrations generally decreased over time, especially throughout 2011, with the exception the acidic Barrels 13 and 17 (Figures 5.2-98, 5.2-99).

Rescan™ Engineers & Scientists

Cadmium concentrations were generally stable in upper panel barrels ranging from 0.000002 to 0.000007 mg/cm in 2011. Cadmium decreased over time in lower panel barrel leachates. Cadmium concentrations in leachates from the acidic Barrels 13 and 17 were two to three orders of magnitude higher than the other lower panel barrels (Figures 5.2-99, 5.2-100).

Chromium concentrations were elevated in leachate from the acidic lower panel barrels 13 and 17, and increased over time. Chromium concentrations in the other barrels were frequently below the detection limit (Figure 5.2-100).

Cobalt concentrations in all barrels except the acidic Barrels 13 and 17 decreased over time (Figure 5.2-101). At the end of 2011, cobalt concentrations in Barrels 4 to 7 ranged from 0.000009 to 0.00005 mg/cm, compared to 0.066 mg/L in the acidic barrels.

Copper concentrations decreased over time for all barrels to less than 0.0002 mg/cm except the acidic Barrels 13 and 17 which had copper concentrations four to five orders of magnitude higher than the other barrels (Figures 5.2-101, 5.2-102).

Lead concentrations increased from 2009 to 2010, and then were decreased in 2011 in all barrels. Lead concentrations were elevated in Barrels 13 and 17 (Figure 5.2-103).

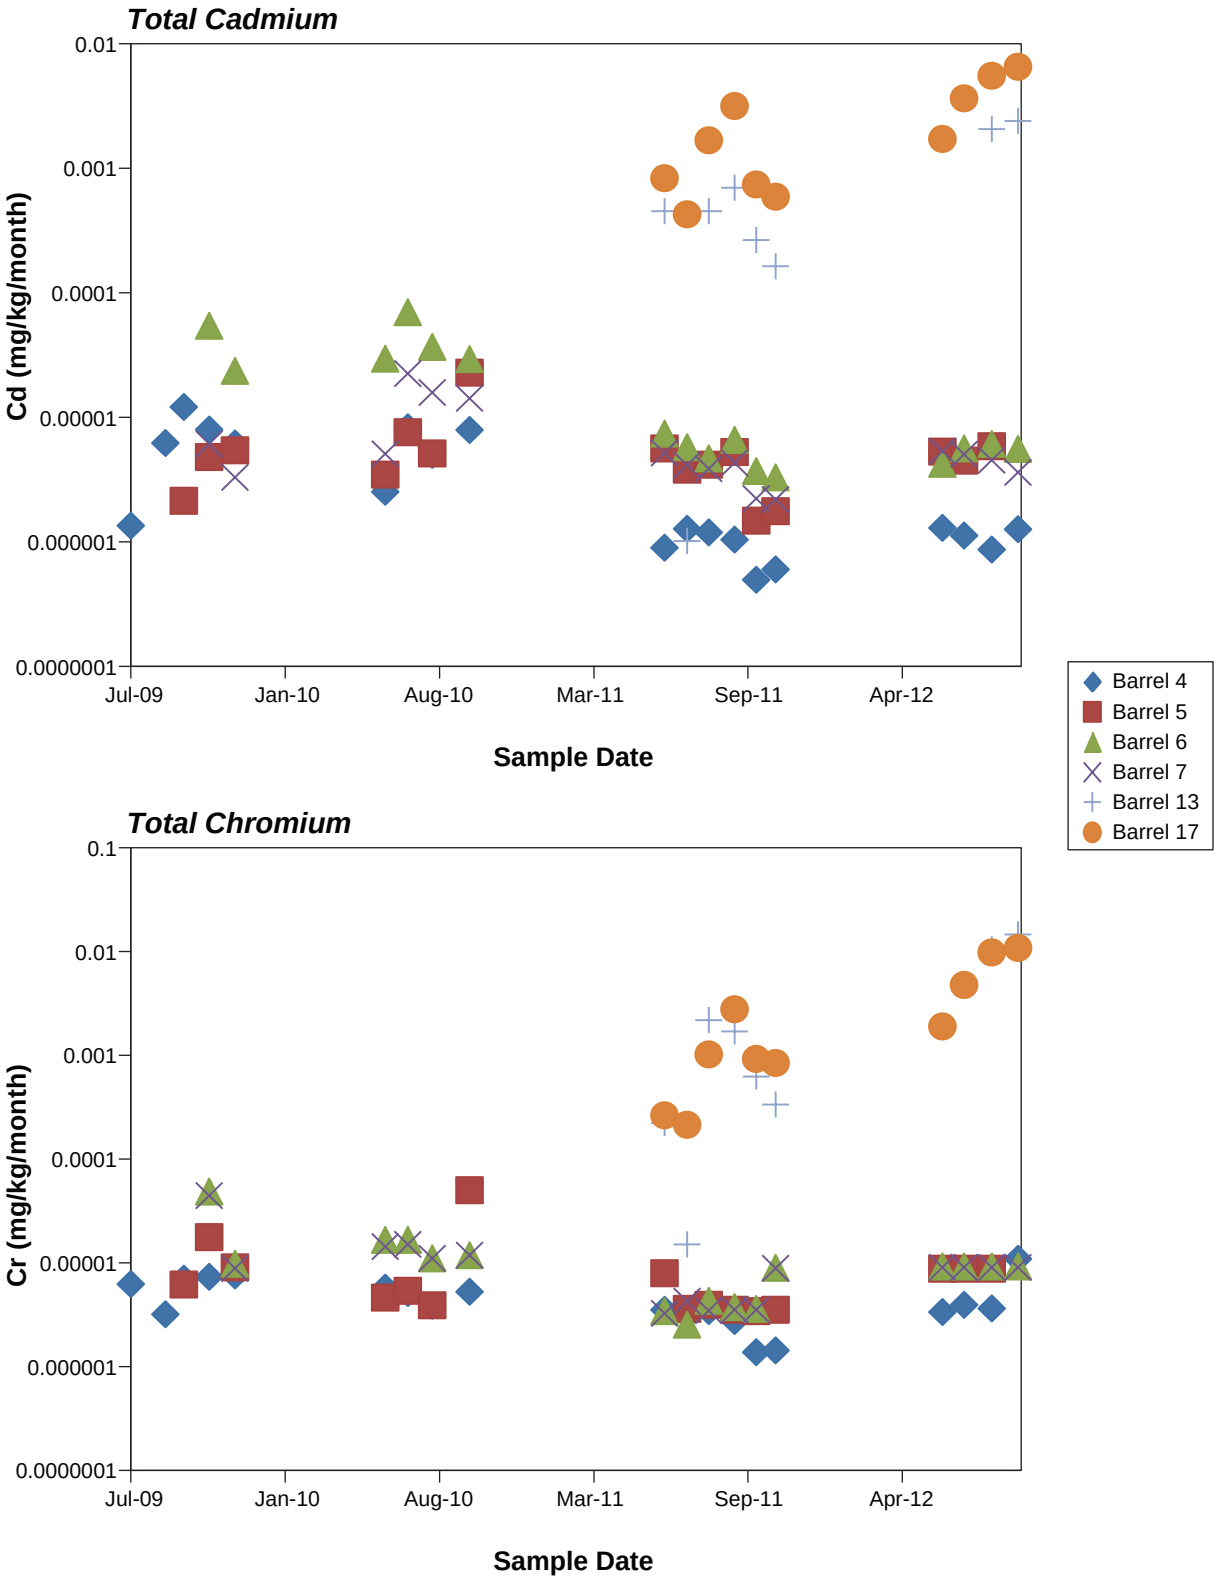
Total mercury concentrations were occasionally elevated in Barrels 5, 13, and 17, but were frequently below detection in all other barrels (Figure 5.2-103).

Molybdenum concentrations were elevated in lower panel Barrel 13. Molybdenum concentrations were generally stable over time for all barrels except for Barrels 13 and 17 which had increasing concentrations (Figure 5.2-102, 5.2-104).

Nickel concentrations were elevated in Barrel 13 and 17. Nickel concentrations generally decreased in other barrels over 2011 (Figure 5.2-104).

Selenium concentrations ranged from 0.0002 to 0.19 mg/cm decreased over time in most barrels with the exception of the acidic lower panel Barrels 13 and 17 (Figure 5.2-105, 5.-2-106).

Silver concentrations ranged from 0.0000005 to 0.0007 mg/cm in lower panel barrels. Silver concentrations decreased over time except in the acidic Barrel 17 (Figure 5.2-105).



Thallium concentrations were elevated in Barrels 13 and 17 relative to the other barrels. Concentrations ranged from 0.000003 to 0.00011 mg/cm. Thallium concentrations in the other barrels were frequently below detection or decreased over time (Figure 5.2-107).

Vanadium concentrations were elevated in leachate from the acidic lower panel Barrel 13. Vanadium concentrations were generally stable in all other lower panel Barrels except the acidic Barrels 13 and 17 where concentrations increased over time (Figure 5.2-107).

Zinc concentrations in leachates from the upper panel barrels stabilized in 2011 around 0.1 mg/cm after variability in 2009 to 2010. Zinc concentrations typically increased over time in leachate from all lower panel barrels (Figures 5.2-106, 5.2-108).

Elements Associated with the Neutralization Potential

Calcium and magnesium concentrations in leachates were comparable and stable across all upper panel barrels ranging from 5.6 to 22 mg/cm. Calcium and magnesium concentrations increased over time in in leachates from most lower panel barrels, with increased variability in the acidic Barrels 13 and 17 (Figures 5.2-109, 5.2-110).

5.2.4 Comparison of Deposit Rock Kinetic Test Results

Table 5.2-8 summarizes the water quality parameters that had elevated concentrations in the three deposit rock kinetic tests: humidity cells, sub-aerial drip columns, and field leach barrels. Metal leaching typically reflected drainage pH and there was generally good agreement across tests. Aluminum, cadmium, copper, selenium, and zinc were elevated most frequently across various model codes and under both near-neutral and acidic pH drainage conditions.

5.3 LEACHATE TESTS

Net Acid Generation (NAG) tests were performed on 49 samples of deposit rock from the Kerr (six samples), Sulphurets (seven samples), and Mitchell Deposits (36 samples). A modified single addition NAG test was carried out using volumes of hydrogen peroxide determined by a preliminary two-cycle sequential NAG test. The results of the modified single addition NAG test were used to identify potentially acid-forming (PAF) and not acid-forming (NAF) material and the percentage of metals associated with sulphide-mineral phases.

5.3.1 Pre-Test Static Results

Pre-test static ABA results are presented in Appendix 5.3-1. Paste pH values ranged from 3.2 (Mitchell QSP lower panel) to 9.9 (Mitchell NM Hazelton Volcanics upper panel) with a median of 7.5, indicating that samples range from currently acid generating to alkaline. The net neutralization potential (NNP) of all 49 samples characterized all samples as PAG.

The results of the metal content analyses of the pre-test samples are presented in Appendix 5.3-2. Table 5.3-1 summarizes the median concentration of selected metals in the model codes from the Kerr, Sulphurets, and Mitchell Deposits.

5.3.2 Leachate Results

5.3.2.1 Acid Generation

Eighty-four deposit rock samples were analysed by a two-cycle sequential NAG test to determine the volume of hydrogen peroxide for a subsequent modified single addition NAG test on a sub-set of 49 samples. Appendix 5.3-3 presents the results from the two-cycle and modified single addition NAG tests and the results are summarized by model code in Table 5.3-2.

Samples designated as PAF had a pH < 4.5 either by the end of Cycle 2 of the two-cycle sequential NAG and/or after the modified single addition NAG tests. Samples designated as uncertain had a pH > 4.5 at the end of Cycle 2 of the two-cycle sequential NAG but were not tested in the modified single addition NAG test. These samples may be NAF if the reaction at the end of Cycle 2 was complete, but this information was not available. No samples were NAF with a pH > 4.5 after the modified single addition NAG test.

5.3.2.2 Metal Leaching

The rapid oxidation of sulphide minerals during the NAG tests liberated metals associated with the sulphide-phase. The metal extraction results indicate that cadmium and copper are substantially associated with sulphide minerals in all model codes. The majority of aluminum and iron in all model codes is not associated with sulphide minerals. The complete leachate dataset is presented in Appendix 5.3-4. The total metal content of the post-test residues is presented in Appendix 5.3-5.

6. Tailing Results

A multi-year (2007 to 2010) comprehensive metallurgical program has been completed by Seabridge on the Kerr, Sulphurets, Mitchell, and Iron Cap deposits of the KSM Project. Historical metallurgical testing was also completed by a number of companies on the Kerr Deposit. The full details of this metallurgical program are discussed in the Preliminary Feasibility Study (Wardrop 2010).

6.1 STATIC TESTS

This section describes the geochemical characteristics of the KSM tailing and its potential for ML/ARD based in the geochemical static test results.

Static tests were performed on 35 tailing samples: Mitchell Rougher (1); Mitchell Rougher-coarse (1); Mitchell Rougher-fine (1); Mitchell Sulphide (pyrite) (1); Mitchell Rougher/Sulphide combined at a ratio equivalent (90:10) to the relative contributions of Rougher and cleaner tailing to the TMF (1); Mitchell/Sulphurets (4); Mitchell/Kerr (16) blended; and Iron Cap (10).

The ABA test results for the KSM tailing are presented Appendix 6.1-1.

6.1.1 Paste pH

The paste pH values of KSM tailing are shown in Figure 6.1-1. Paste pH values in Mitchell/Kerr, Mitchell/Sulphurets Rougher tailing ranged from pH 7.8 to pH 11.1 with median values of pH 9. The paste pH values for Iron Cap Rougher tailing ranged from pH 8.4 to pH 8.6 with median values of pH 8.8.

The paste pH of the Mitchell Sulphide tailing was acidic (5.8) while the Mitchell Rougher tailing range was basic (pH 7.9 to pH 8.2). The Mitchell Rougher/Sulphide tailing shows a paste pH slightly above 6.0.

6.1.2 Sulphur Species

The total-sulphur content of KSM tailing is shown in Figure 6.1-2. Total-sulphur content of Mitchell/Kerr Rougher tailing ranged from 0.19% to 0.48% with a median content of 0.35%, while total-sulphur contents of Mitchell/Sulphurets Rougher tailing ranged from 0.11% to 0.19% with a median content of 0.12%. Total-sulphur contents of Iron Cap Rougher tailing ranged from 0.05% to 0.08% with a median content of pH 0.07%.

Total-sulphur content of Mitchell Sulphide tailing was 22.40% and total-sulphur content of Mitchell Rougher/Sulphide tailing was 3.13%. The Mitchell Rougher tailing total-sulphur range was 0.21% to 0.38%.

The sulphide-sulphur content of the KSM tailing is shown in Figure 6.1-3. Sulphide-sulphur content of Mitchell/Kerr Rougher tailing ranged from 0.06 % to 0.16% with a median content of 0.13%, while sulphide-sulphur content of Mitchell/Sulphurets Rougher tailing ranged from 0.06 % to 0.11% with a median content of 0.08%. Sulphide-sulphur content of Iron Cap Rougher tailing ranged from 0.05% to 0.06% with a median content of 0.05.

Sulphide-sulphur content of Mitchell Sulphide tailing was 20.2% and sulphide-sulphur content of Mitchell Rougher/Sulphide tailing was 2.32%. The Mitchell Rougher tailing sulphide-sulphur range was 0.04% to 0.08%.

Tailing - Sulphide-Sulphur Concentrations

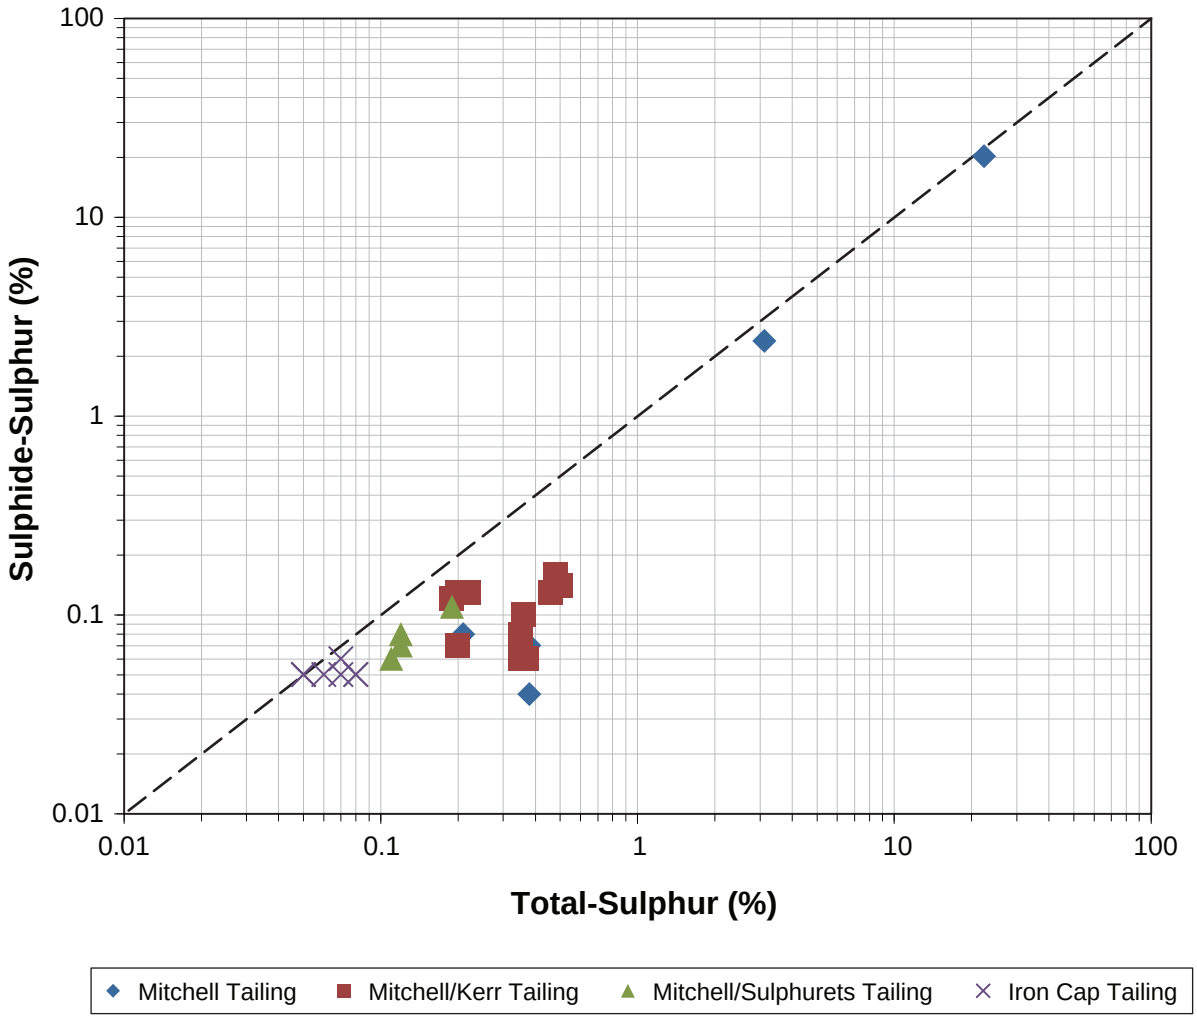
Figure 6.1-3

Rescan™
Engineers & Scientists

The plot of sulphide-sulphur versus total-sulphur (Figure 6.1-4) shows the distribution of those two sulphur species within the various tailing types. The results indicate that Mitchell Sulphide, Mitchell Rougher/Sulphide have the highest total-sulphur and sulphide-sulphur concentrations and show the strongest correlation between sulphide-sulphur and total-sulphur. The weaker correlation between the total-sulphur and sulphide-sulphur content in Mitchell Rougher, Mitchell/Kerr, Mitchell/Sulphurets, and the Iron Cap Rougher tailing reflects metallurgical processing and the presence of non-sulphide-sulphur species. Figure 6.1-5 shows the relationship between acid-soluble sulphate-sulphur and total-sulphur concentrations, indicating that some of the samples have high concentrations of acid-soluble sulphate-sulphur.

6.1.3 Neutralization Potential

NP of the KSM tailing is shown in Figure 6.1-6. NP values of Mitchell/Kerr Rougher tailing ranged from 12 kg $CaCO_3$/t to 26 kg $CaCO_3$/t with a median value of 16 kg $CaCO_3$/t, while NP values of Mitchell/Sulphurets Rougher tailing ranged from 41 kg $CaCO_3$/t to 46 kg $CaCO_3$/t with a median value of 43 kg $CaCO_3$/t. NP values of Iron Cap Rougher tailing ranged from 24 kg $CaCO_3$/t to 28 kg $CaCO_3$/t with a median value of 27 kg $CaCO_3$/t.



NP value of Mitchell Sulphide tailing was 6 kg $CaCO_3$/t and NP value of Mitchell Rougher/Sulphide tailing was 22 kg $CaCO_3$/t. The Mitchell Rougher tailing NP range was 28 kg $CaCO_3$/t to 31 kg $CaCO_3$/t.

The Mitchell Sulphide tailing exhibited 6 kg $CaCO_3$/t of unavailable NP at the time of the test (Figure 6.1-7). The NP was adjusted by this estimate of unavailable NP to calculate an adjusted NP. The adjusted NP of Mitchell Sulphide tailing was 0 kg $CaCO_3$/t, because it was acid generating at the time of the paste pH test.

The correlation between Bulk Sobek NP and Inorg NP is shown in Figure 6.1-8. The Inorg NP shows a good correlation to Bulk Sobek NP in Mitchell/Sulphurets Rougher tailing, some of Mitchell/Kerr Rougher, and Mitchell tailing (with the exception of Mitchell Rougher-coarse tailing and Mitchell Sulphide tailing), suggesting that most of the Sobek NP occurs as carbonate minerals. Therefore the Inorg NP can be estimated from inorganic carbon analyses as a reasonable surrogate to the Sobek NP for estimation of the available NP in these tailing. The Inorg NP shows a poor correlation to Sobek NP in the Iron Cap Rougher tailing, suggesting Sobek NP is comprised of a mixture of carbonate and non-carbonate minerals.

A plot of a Ca CaNP, assuming that the elemental calcium is present as calcite, versus Bulk Sobek NP is shown in Figure 6.1-9. The Ca CaNP values show a good correlation with the Sobek NP values in most of the samples with the exception of some samples from Mitchell/Kerr Rougher tailing and Mitchell Sulphide tailing, indicating that most of the available Sobek NP in the KSM tailing occurs as calcium carbonate minerals. Some samples from Mitchell/Kerr Rougher tailing exhibit poor correlation, indicating the presence of a greater proportion of calcium from non-carbonate mineral phases.

A plot of a CaMg CaNP, assuming that the elemental calcium and magnesium is present as dolomite, versus Bulk Sobek NP is shown in Figure 6.1-10. The correlation between CaMg CaNP and Sobek NP was poorer than for Ca CaNP, indicating that a measurable portion of CaMg CaNP is not providing neutralization or is unreactive. This poor correlation indicates that magnesium occurs predominantly in non-carbonate magnesium-bearing mineral phases. Therefore the CaMg CaNP cannot be used reliably for estimating the available NP in the KSM Deposits.

6.1.4 Sulphide Net Potential Ratios

Adjusted SNPR values for the KSM tailing are shown in Figure 6.1-11. The adjusted SNPR values for Mitchell/Kerr Rougher tailing range from a minimum of 2.9 to a maximum of 13.3, with a mean of 6.5 and a median of 3.7. The adjusted SNPR values for Mitchell/Sulphurets Rougher tailing range from a minimum of 11.9 to a maximum of 24.5, with a mean of 18.3 and a median of 18.4. The adjusted SNPR values for Iron Cap Rougher tailing range from a minimum of 14.9 to a maximum of 17.9, with a mean of 16.7 and a median of 16.9. Mitchell Rougher tailing adjusted SNPR values range from 0.01 (Mitchell Sulphide) to 24.8 (Mitchell Rougher-fines).

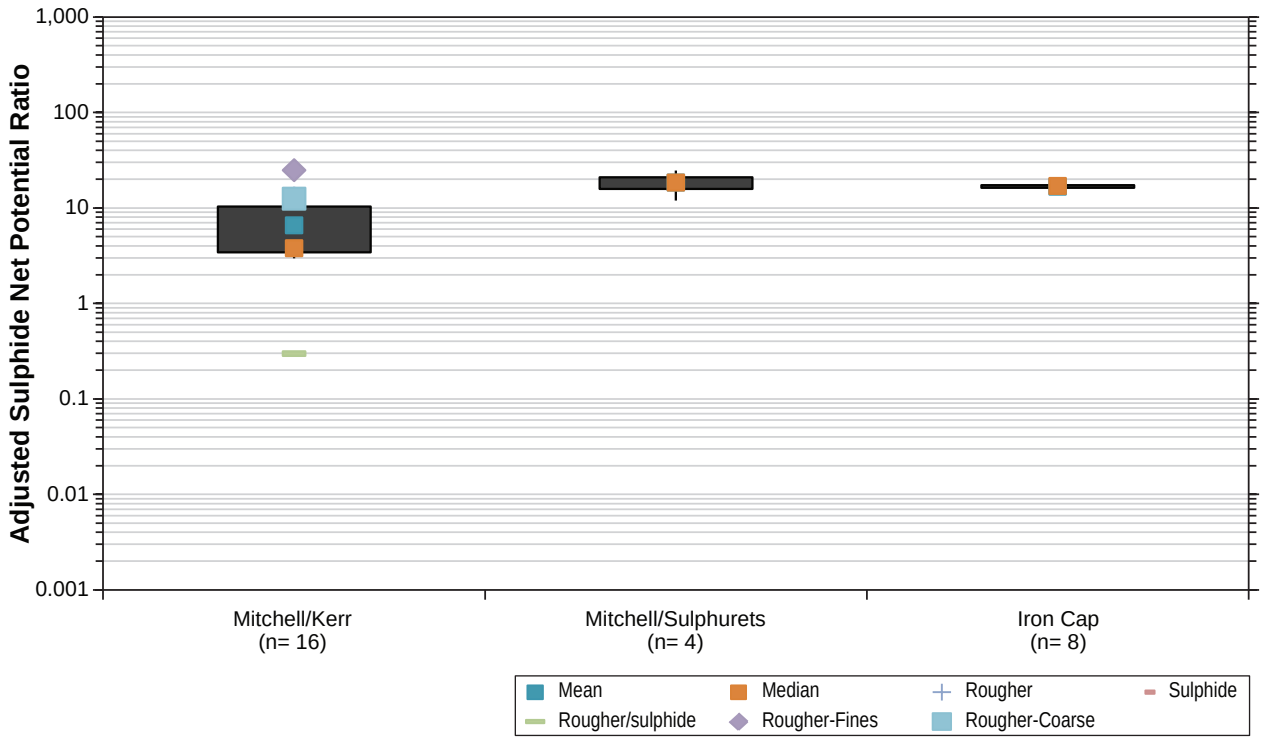
The majority of the KSM tailing are not-PAG with the exception of Mitchell Sulphide tailing and Mitchell Rougher/Sulphide tailing. Mitchell Sulphide tailing sample exhibited a default adjusted SNPR of 0.01, indicating that the sample had NP equal to or lower than 6 $kgCaCO_3/t$, and that the onset of acidic conditions is likely to be rapid in this sample. Mitchell Rougher/Sulphide tailing sample has an adjusted SNPR of 0.3, indicating it is PAG.

The relationship between paste pH and adjusted SNPR of KSM tailing samples is shown in Figure 6-1-12. Samples with adjusted SNPR values of 0.01 were associated with acidic pH, indicating that the Mitchell Sulphide tailing sample is in an advanced stage of acid generation (acidic sample).

The relationship between sulphide-sulphur and adjusted SNPR of KSM tailing samples is shown in Figure 6.1-13. It indicates that the samples with a combination of sulphide-sulphur greater than 0.1% and an adjusted SNPR<2 are the most likely to be net ARD generating.

6.1.5 Whole Rock and Solid-phase Elemental Analysis

The multi-element concentrations of KSM tailing were measured by ICP-MS analysis after strong four-acid digestion and by XRF whole-rock analysis. The results of these analyses are found in Appendix 6.1-1.



Trace elements analysis by ICP-MS provides a measure of concentrations of various elements within the sample. When compared to known concentrations within the Earth's crust, these analyses can be used to determine which elements are present in anomalous quantities which increases the likelihood of mobilization by leaching. In this report, elevated concentrations are defined as concentrations exceeding three times average crustal abundance. Tailing solid-phase analyses were compared to the crustal abundance for shale.

While the comparison of solid-phase elemental concentrations to three times the average crustal abundance can provide an indication of elevated elements, it does not determine susceptibility to weathering, weathering rates or aqueous concentrations under site-specific conditions. However, the identification of elevated solid-phase elemental concentrations relative to crustal abundances provides an early-stage screening tool for identification of important mineral phases and potential constituents of concern in leach extraction and/or kinetic testing.

Mitchell Sulphide tailing was comprised mostly of oxide-equivalents of SiO_2 and Fe_2O_3 with lesser but still significant amounts of Al_2O_3. Mitchell Rougher/Sulphide tailing was comprised of oxide-equivalents of SiO_2 and Al_2O_3, with lesser but still significant amounts of Fe_2O_3.

Mitchell Rougher tailing were comprised mostly of SiO_2 and Al_2O_3, with lesser but still significant amounts of Fe_2O_3 and K_2O.

Mitchell/Kerr Rougher tailing and Mitchell/Sulphurets Rougher tailing were comprised mostly of oxide-equivalents of Al_2O_3 and BaO with lesser but still significant amounts of K_2O and MgO.

Iron Cap Rougher tailing and Mitchell/Sulphurets Rougher tailing were comprised mostly of oxide-equivalents of Al_2O_3 and BaO with lesser but still significant amounts of MgO, CaO, and Fe_2O_3.

Table 6.1-1 shows the statistical summary of the elements with median values exceeding three times the average crustal abundance for the KSM tailing samples.

The elements frequently exceeding three times average shale crustal abundance in Mitchell Sulphide tailing are silver, arsenic, cadmium, copper, iron, molybdenum, sulphur, antimony, and selenium. Elements frequently exceeding three times shale crustal abundance in Mitchell Rougher/Sulphide tailing are silver, cadmium, copper, molybdenum, sulphur, and selenium. Elements frequently exceeding three times shale crustal abundance in Mitchell Rougher tailing are silver, copper, molybdenum, and selenium.

Elements frequently exceeding three times shale crustal abundance in Mitchell/Kerr Rougher tailing are silver, copper, and selenium.

Elements frequently exceeding three times shale crustal abundance in Mitchell/Sulphurets Rougher tailing are silver, copper and molybdenum.

Elements frequently exceeding three times shale crustal abundance in Iron Cap Rougher tailing are silver, copper and antimony.

6.1.6 Mineralogy

The mineralogy of the KSM tailing samples submitted for humidity cell tests was analyzed by Rietveld XRD analysis (Appendix 6.1-2), and QEMSCAN analysis (Appendix 6.1-3). A comparison between these two analyses is shown in Appendix 6.1-4.

Pyrite was the main sulphide-bearing mineral occurring in Mitchell Sulphide tailing (42.5 wt %) with lesser amounts of chalcopyrite (1.4 wt %) and molybdenite (0.2 wt %). The main gangue mineral identified in the Mitchell Sulphide tailing was quartz (25.5 wt %) followed by muscovite (17.0 wt %), the magnesium-bearing aluminosilicate clinochlore (3.7 wt %), K-feldspar (3.4 wt %), and calcium–bearing aluminosilicate plagioclase (3.2 wt %). Minor amounts of calcite (0.7 wt %), ankerite/dolomite (0.7 wt %) and gypsum (0.7 wt %) were also identified.

A small amount of pyrite (0.2 wt %) was identified in Mitchell Rougher tailing. The main gangue mineral identified in Mitchell Rougher tailing was quartz (56.0 wt %) followed by muscovite (23.0 wt %), plagioclase (7.0 wt %), clinochlore (4.6 wt %) and K-feldspar (3.6 wt %). Calcite, ankerite/dolomite and gypsum were identified in lesser amounts, but greater than the amounts identified in Mitchell Sulphide tailing. QEMSCAN analyses identified minor amounts of the zinc-bearing sulphide mineral sphalerite (0.1%) and the lead-bearing sulphide mineral galena (0.1%).

Pyrite (4.5 wt %) and minor chalcopyrite (0.2 wt %) were the sulphide-bearing minerals identified in the Mitchell Rougher/Sulphide tailing. The type and amounts of non-sulphide minerals were similar to the minerals identified in the Mitchell Rougher tailing.

Some differences in the mineralogy were identified for the Mitchell Rougher-fine and Mitchell Rougher-coarse tailing. There was a minor amount of pyrite (0.2 wt %) in the Mitchell Rougher-fine and the amount of quartz was greater in the Mitchell Rougher-coarse.

In general plagioclase and feldspar are the dominant silicate minerals contributing NP in the Mitchell tailing samples. Calcite and ankerite/magnesite are the only carbonate minerals identified in the Mitchell and Mitchell/Sulphurets Rougher tailing. The quantitative analyses show trace quantities of calcite (0.3 to 2.3%) in all the samples.

6.1.7 Particle Size Analysis

The particle size distribution of the tailing samples submitted for humidity cell tests was analyzed by the wet sieving method (Mitchell tailing) and by laser diffraction method (Mitchell/Kerr Rougher and Mitchell/Sulphurets Rougher tailing). Appendix 6.1-5 presents the particle size analyses results.

Mitchell tailing showed a broad range of particle size distributions. Analysis of the Mitchell Rougher-fine tailing showed that 50% by weight was finer than 5.0 microns, and 80% by weight was finer than 12.0 microns. The Mitchell Rougher tailing analysis showed that 50% by weight was finer than 44 microns, and 80% by weight was finer than 75 microns. The Mitchell Rougher-coarse tailing analysis showed that approximately 50% by weight was finer than 100 microns, and approximately 80% by weight was finer than 150 microns.

Mitchell/Kerr Rougher tailing analysis showed that 50% by volume was finer than 12 microns to 16 microns, and 80% by volume was finer than 63 microns to 84 microns. Analysis of the Mitchell/Sulphurets Rougher tailing showed that 50% by volume was finer than 20 microns, and 80% by volume was finer than 89 microns.

6.1.8 Coarse versus Fine Mitchell Rougher Tailing

The static test results of the Mitchell Rougher-coarse tailing and Mitchell Rougher-fine tailing were similar to the Mitchell total Rougher. The Mitchell Rougher-fine and Mitchell total Rougher static test results have a stronger correlation; both representing tailing material that will be deposited in the flotation tailing cells in the summer and winter respectively. The Mitchell Rougher-coarse tailing static test results were also very similar and represent cyclone tailing material proposed to be used for TMF dam construction during summer months.

The Mitchell Rougher-coarse and Mitchell Rougher-fine fraction ABA results show no variation in the paste pH. The total-sulphur concentration in the fine fraction (0.38%) was higher than the concentration in the coarse fraction (0.21%). The sulphide-sulphur concentration in the fine and coarse fractions tested were 0.04% and 0.08%, respectively. The fine fraction and coarse fraction tailing show sulphate-sulphur concentrations of 0.37% and 0.15%, respectively.

The Sobek NP of both the Rougher-coarse and Rougher-fine tailing was 31 kg $CaCO_3$/t. There was better agreement between the Inorg NP and Sobek NP values for the Rougher-fines tailing (difference of 4 kg $CaCO_3$/t) than the Rougher-coarse tailing (difference of 16 kg $CaCO_3$/t).

The SNPR values for the Rougher-coarse and Rougher-fine fractions were above 10.0. These SNPR values indicate that the Rougher-coarse and Rougher-fine tailing are not-PAG.

6.2 KINETIC TESTS

6.2.1 Humidity Cells

6.2.1.1 Pre-test Static Test Results

The results of the static tests of the tailing and tailing composites used in humidity cells are presented in Section 6.1.

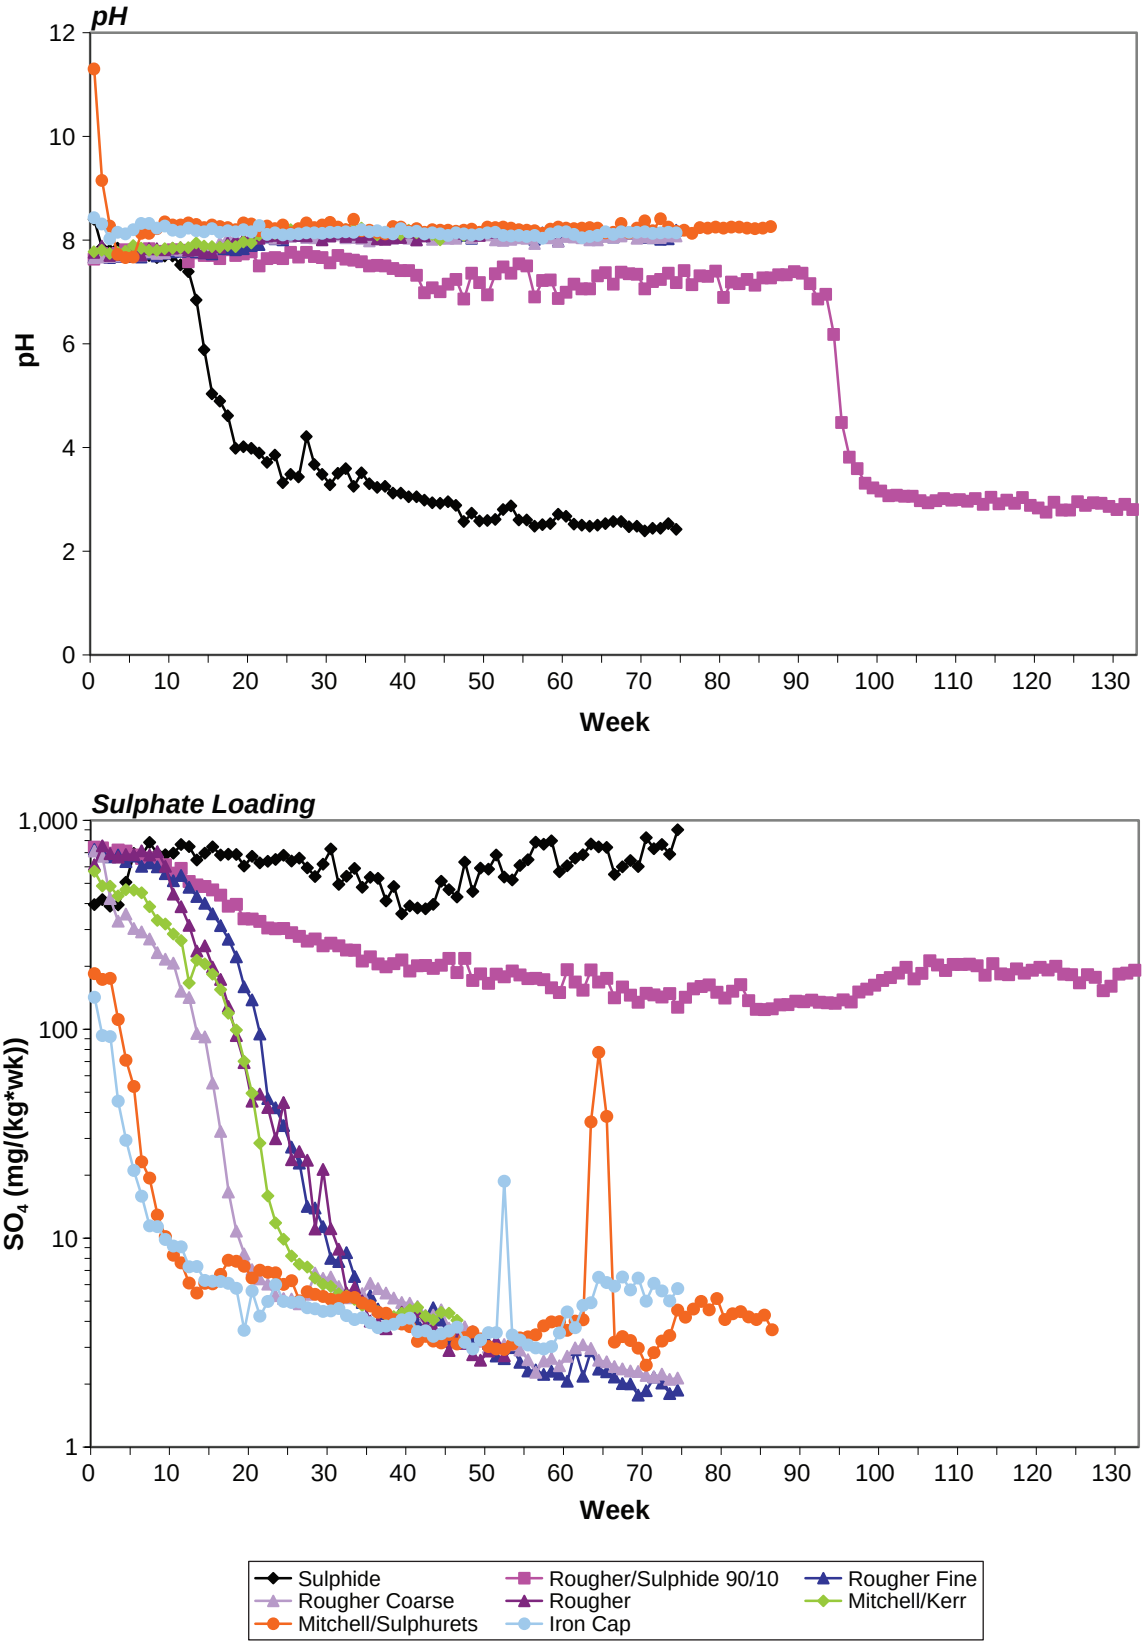
6.2.1.2 Kinetic Test Results

This section of the report incorporates results collected up till the end of July 2012. The following discussion presents an assessment of the analyses of leachate from the tailing humidity cells for:

- Indicators of acid generation (pH, sulphate, acidity, and alkalinity);
- Elements that contribute to acidity (aluminum, iron, and manganese);
- Barium which is most commonly associated with barite ($BaSO_4$), a highly insoluble mineral;
- Trace elements with elevated concentrations in the last 10 weekly cycles relative to water quality guidelines. Identification of these elements can be used to inform treatment design decisions and water quality modelling; and
- Calcium and magnesium which commonly occur in carbonate mineral phases and are associated with the neutralization potential.

The detection limits for the metal analyses method are presented in Section 4 (Table 4.4-1). The detection limits have been lowered during the humidity cells operation period.

The leach rates over time for the above parameters for all humidity cells are graphically presented. The complete data set for humidity cell leachate concentrations is presented in Appendix 6.2-1. The leach rates representing concentrations below the detection limit are shown as a sequence of constant values. Leach rates for parameters additional parameters are presented in Appendix 6.2-2.



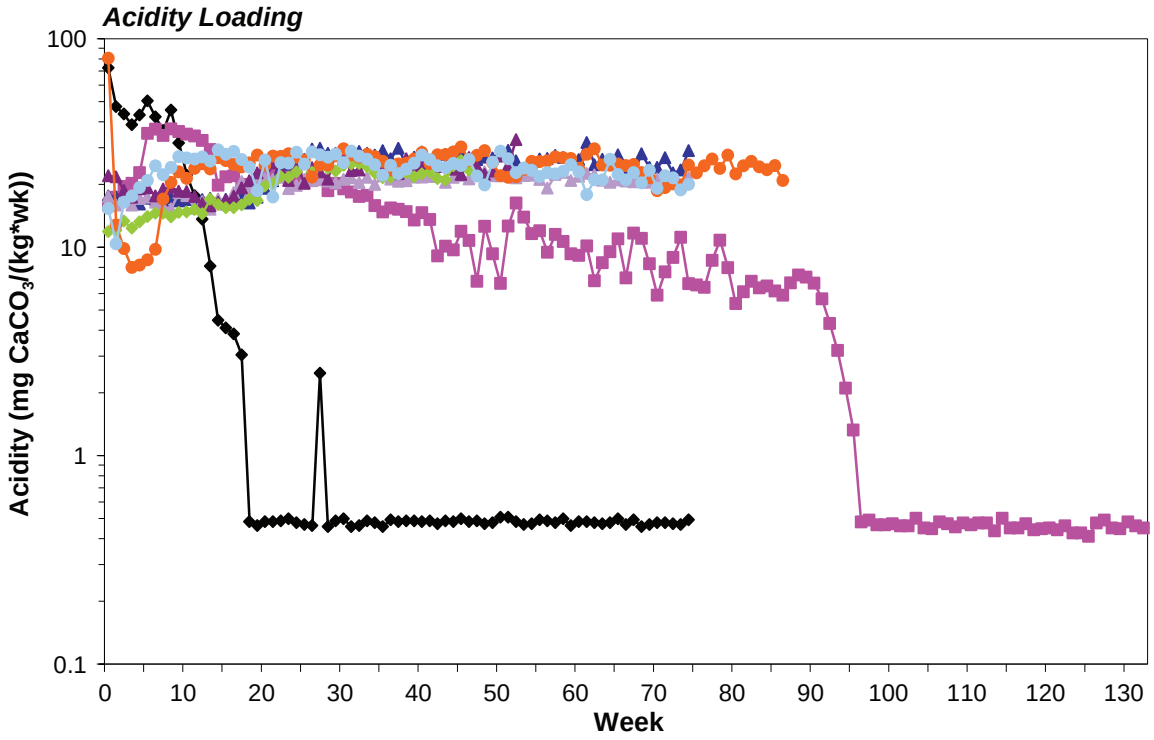
These data represent eight humidity cells that were operated for 52 to 148 weeks for the following tailing samples: Sulphide (Mitchell Sulphide), Rougher/Sulphide (Mitchell Rougher/Sulphide 90/10), Rougher-fine (Mitchell Rougher-fine), Rougher-coarse (Mitchell Rougher-coarse), Rougher (Mitchell Rougher), Mitchell/Kerr, Mitchell/Sulphurets, and Iron Cap. Mitchell tailing chemistry is expected to dominate the chemistry of the TMF.

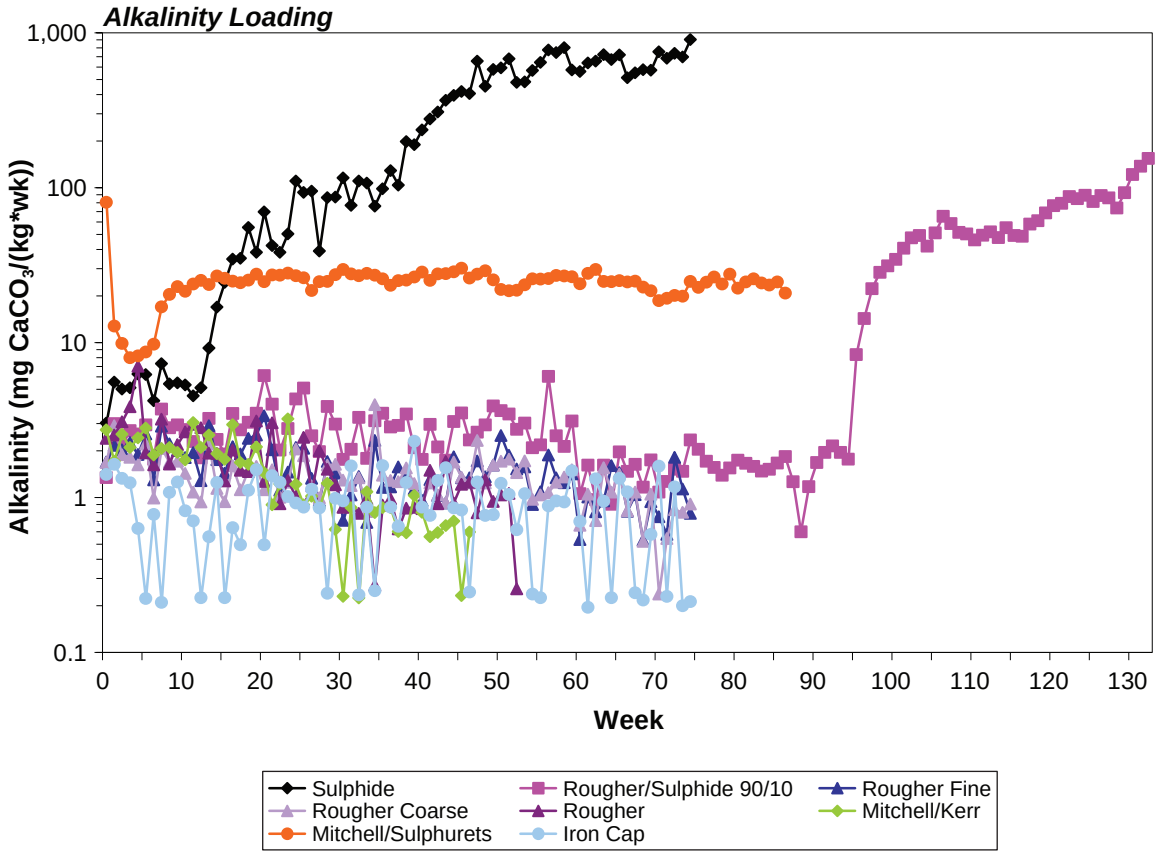
pH, Sulphate, Acidity, and Alkalinity

Initial pH values of tailing humidity cells leachate were near-neutral with the exception of the initial alkaline pH 11.3 observed in the Mitchell/Sulphurets humidity cell. The initial flush reduced the high pH by week 3 and leachate from the Rougher-fine, Rougher-coarse, Rougher, Mitchell/Kerr, Mitchell/Sulphurets, and Iron Cap humidity cells remained around pH 8 for the remaining weekly cycles. The pH in the Sulphide humidity cell decreased rapidly at week 12 and stabilized at pH 2.5. The pH gradually decreased in the Rougher/Sulphide humidity cell between weeks 12 and 89 before sharply decreasing to a stable pH of 3 (Figure 6.2-1).

Sulphate production rates in the near-neutral humidity cells decreased by two orders of magnitude over 46 to 73 weeks. Iron Cap sulphate production rates increased at week 57. Sulphate production rates in the Sulphide humidity cell ranged from 700 to 1000 mg/kg/wk. Steady state sulphate production rates in the Rougher/Sulphide humidity cell were approximately 200 mg/kg/wk to week 133, increasing rapidly to 681 mg/kg/wk in the last 15 weeks. The higher sulphate production rates in the acidic humidity cells are consistent with sulphide oxidation driving the pH decrease (Figure 6.2-1).

Acidity production was highly variable and frequently below detection in the near-neutral humidity cells with the exception of Mitchell/Sulphurets (steady state acidity production 25 mg $CaCO_3$/kg/wk). Acidity production in the Sulphide humidity cell increased over time, while increased acidity production in the Rougher/Sulphide humidity cell was not observed until week 89 at the time of the pH decrease. Alkalinity production rates in the near-neutral humidity cells remained constant at approximately 25 mg $CaCO_3$/kg/wk. Alkalinity was below the detection limit after week 18 and week 96 in the Sulphide and Rougher/Sulphide humidity cells, respectively (Figure 6.2-2).





SEABRIDGE GOLD
KSM PROJECT

Acidity and Alkalinity Production, Tailing Humidity Cells

Figure 6.2-2

Rescan™ Engineers & Scientists

Elements that Contribute to Acidity

Aluminum leach rates increased over time in the Sulphide humidity cell to 12.3 mg/kg/wk. Aluminum leach rates increased at the time of the pH decrease in the Rougher/Sulphide humidity cell and stabilized at 1.26 mg/kg/wk around week 127. A rapid increase in Aluminum leach rates to 13.74 mg/kg/wk is observed after week 127. Aluminum leach rates in the near-neutral humidity cells ranged from 0.014 to 0.043 mg/kg/wk (Figure 6.2-3).

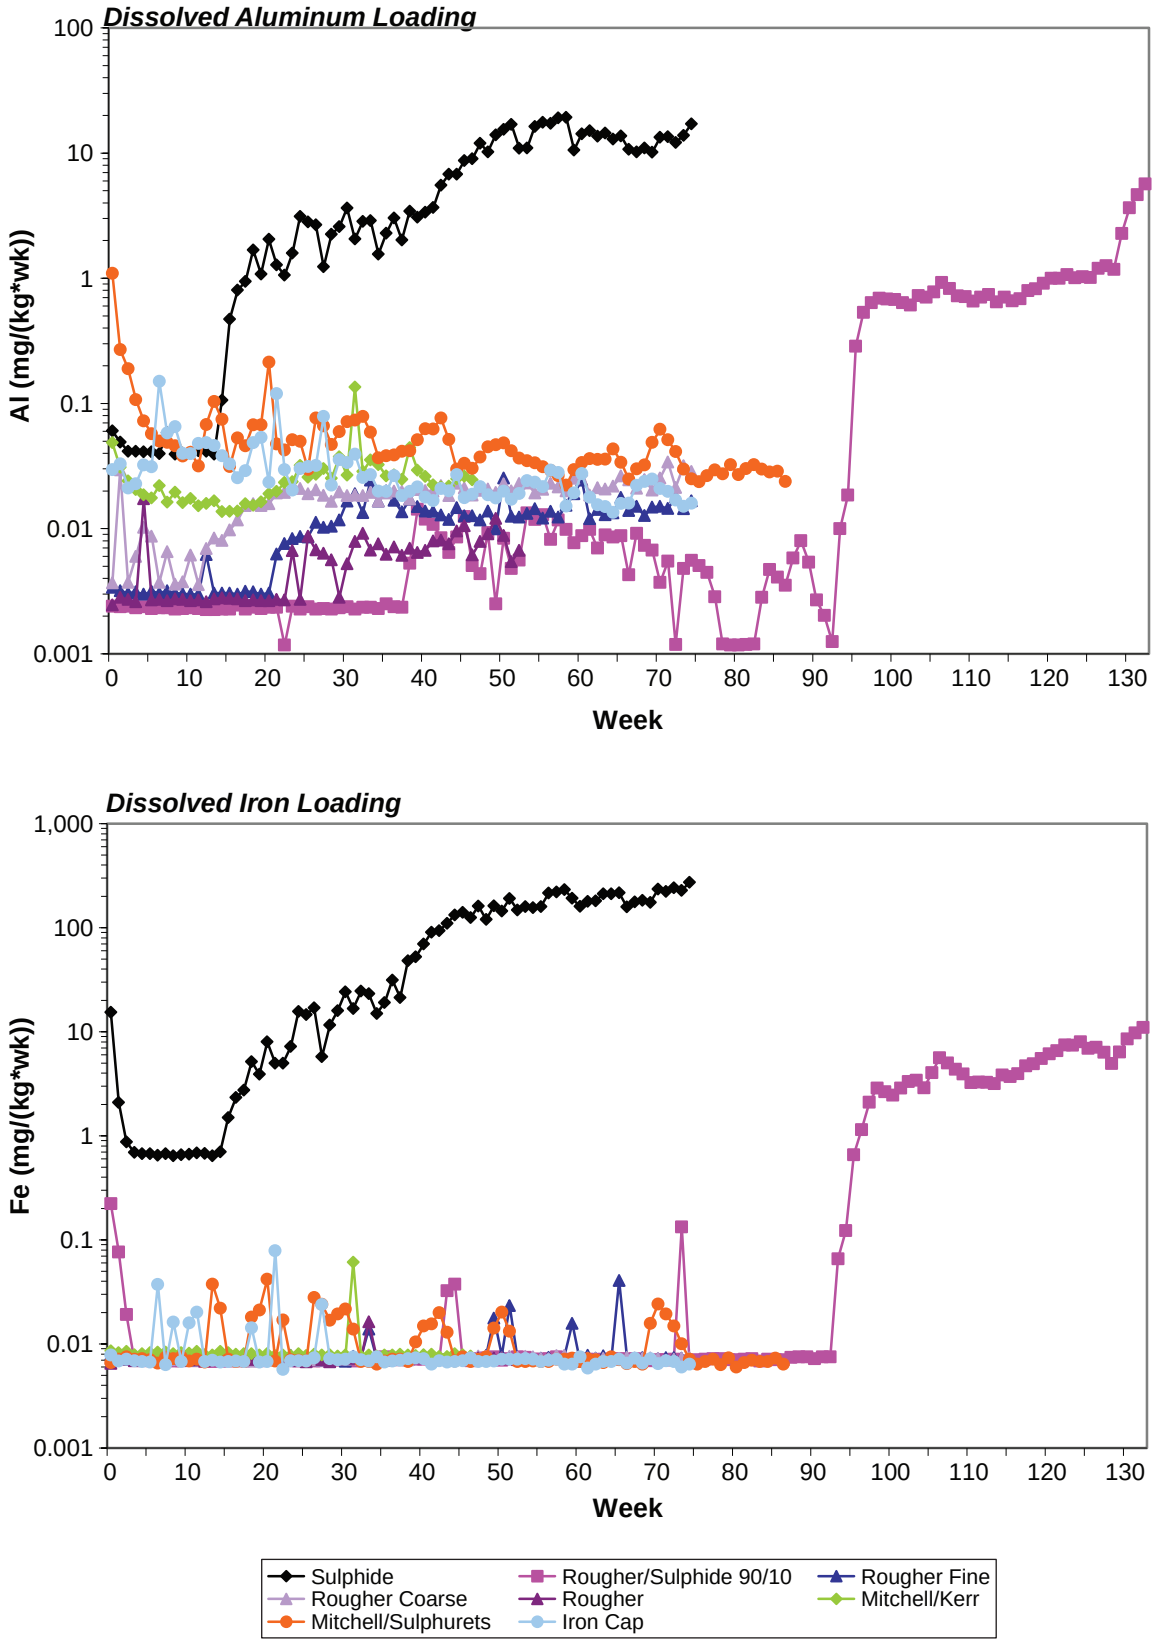
Iron concentrations in the leachate from the near-neutral humidity cells were frequently below detection. Iron leach rates increased over time in the Sulphide humidity cell to 272 mg/kg/wk. Iron leach rates increased gradually to 7 mg/kg/wk in the Rougher/Sulphide humidity cell to week 127 (Figure 6.2-3). A further rapid increase in iron leach rates to 186 mg/kg/wk was observed after week 127.

Manganese leach rates were variable over time and stabilized at approximately 0.9 mg/kg/wk. Leach rates in the Rougher/Sulphide humidity cell increased over time to week 125, and subsequently decreased (Figure 6.2-4).

Barium

Barium leach rates were stable over time in the acidic humidity cells and ranged from 0.005 to 0.007 mg/kg/wk. The low barium concentrations likely reflected barium precipitation as barite. Barium leach rates in the near-neutral humidity cells increased over time and ranged from 0.06 to 0.25 mg/kg/wk in the last 10 weeks. Decreased barium leaching occurred in Mitchell/Sulphurets and Iron Cap humidity cells after week 67 and 59, respectively (Figure 6.2-4).

Trace Elements



Arsenic concentrations in the Rougher-fine, Rougher-coarse, and Rougher humidity cells were frequently below detection. Arsenic leach rates in the Sulphide humidity cell increased after week 41 when the pH decreased below 3 and were highly variable. Leach rates in the Rougher/Sulphide humidity cell increased to 0.0003 mg/kg/wk between weeks 100 and 127, then increased again to 0.0018 mg/kg/wk at week 143 due to decreased pH (Figure 6.2-5).

Cadmium leach rates were variable in the Sulphide humidity cell but were relatively stable after week 48 at 0.05 mg/kg/wk. Leach rates in the Rougher/Sulphide humidity cell increased after week 89 to stabilize at 0.001 mg/kg/wk. Cadmium leach rates in the Rougher/Sulphide humidity cell increased to 0.037 mg/kg/wk from week 113 to week 129, and subsequently decreased. The near-neutral leach rates were two orders of magnitude less and were approximately 0.00001 mg/kg/wk (Figure 6.2-5).

Chromium concentrations were below detection in the near-neutral humidity cells. Chromium leach rates increased over time in the Sulphide humidity cell after week 25. Chromium leach rates increased after week 93 in the Rougher/Sulphide humidity cells to stable leach rates of 0.005 mg/kg/wk to week 127. A rapid increase in leach rates to 0.20 mg/kg/wk was observed at week 144 (Figure 6.2-6).

Cobalt concentrations were below detection in the near-neutral humidity cells. Steady state leach rates in the Sulphide humidity cell were 0.08 mg/kg/wk. Cobalt leach rates increased at week 91 in the Rougher/Sulphide to 0.09 mg/kg/wk (Figure 6.2-6).

Copper leach rates sharply increased at week 9 in the Sulphide humidity cell and stabilized at 32 mg/kg/wk. Steady-state leach rates in the Rougher/Sulphide humidity cell after the increase at week 90 were 0.5 mg/kg/wk. Copper leach rates in the Rougher/Sulphide humidity cell increased to 17.5 mg/kg/wk from week 113 to week 131, and subsequently decreased. Copper leach rates in the near-neutral humidity cells ranged from below detection in the Rougher humidity cell to 0.0007 mg/kg/wk in the Rougher-coarse humidity cell (Figure 6.2-7).

Copper and Fluoride Leach Rates, Tailing Humidity Cells

Figure 6.2-7

Rescan™ Engineers & Scientists

Fluoride leach rates in the Sulphide humidity cell increased at week 37 and stabilized at approximately 0.9 mg/kg/wk. Fluoride leach rates increased at week 123 in the Rougher/Sulphide humidity cell to a maximum of 1.00 mg/kg/wk at week 136, and subsequently decreased. Iron Cap fluoride leach rates were stable over time at 0.3 mg/kg/wk. Fluoride leach rates in the other humidity cells generally decreased over time (Figure 6.2-7).

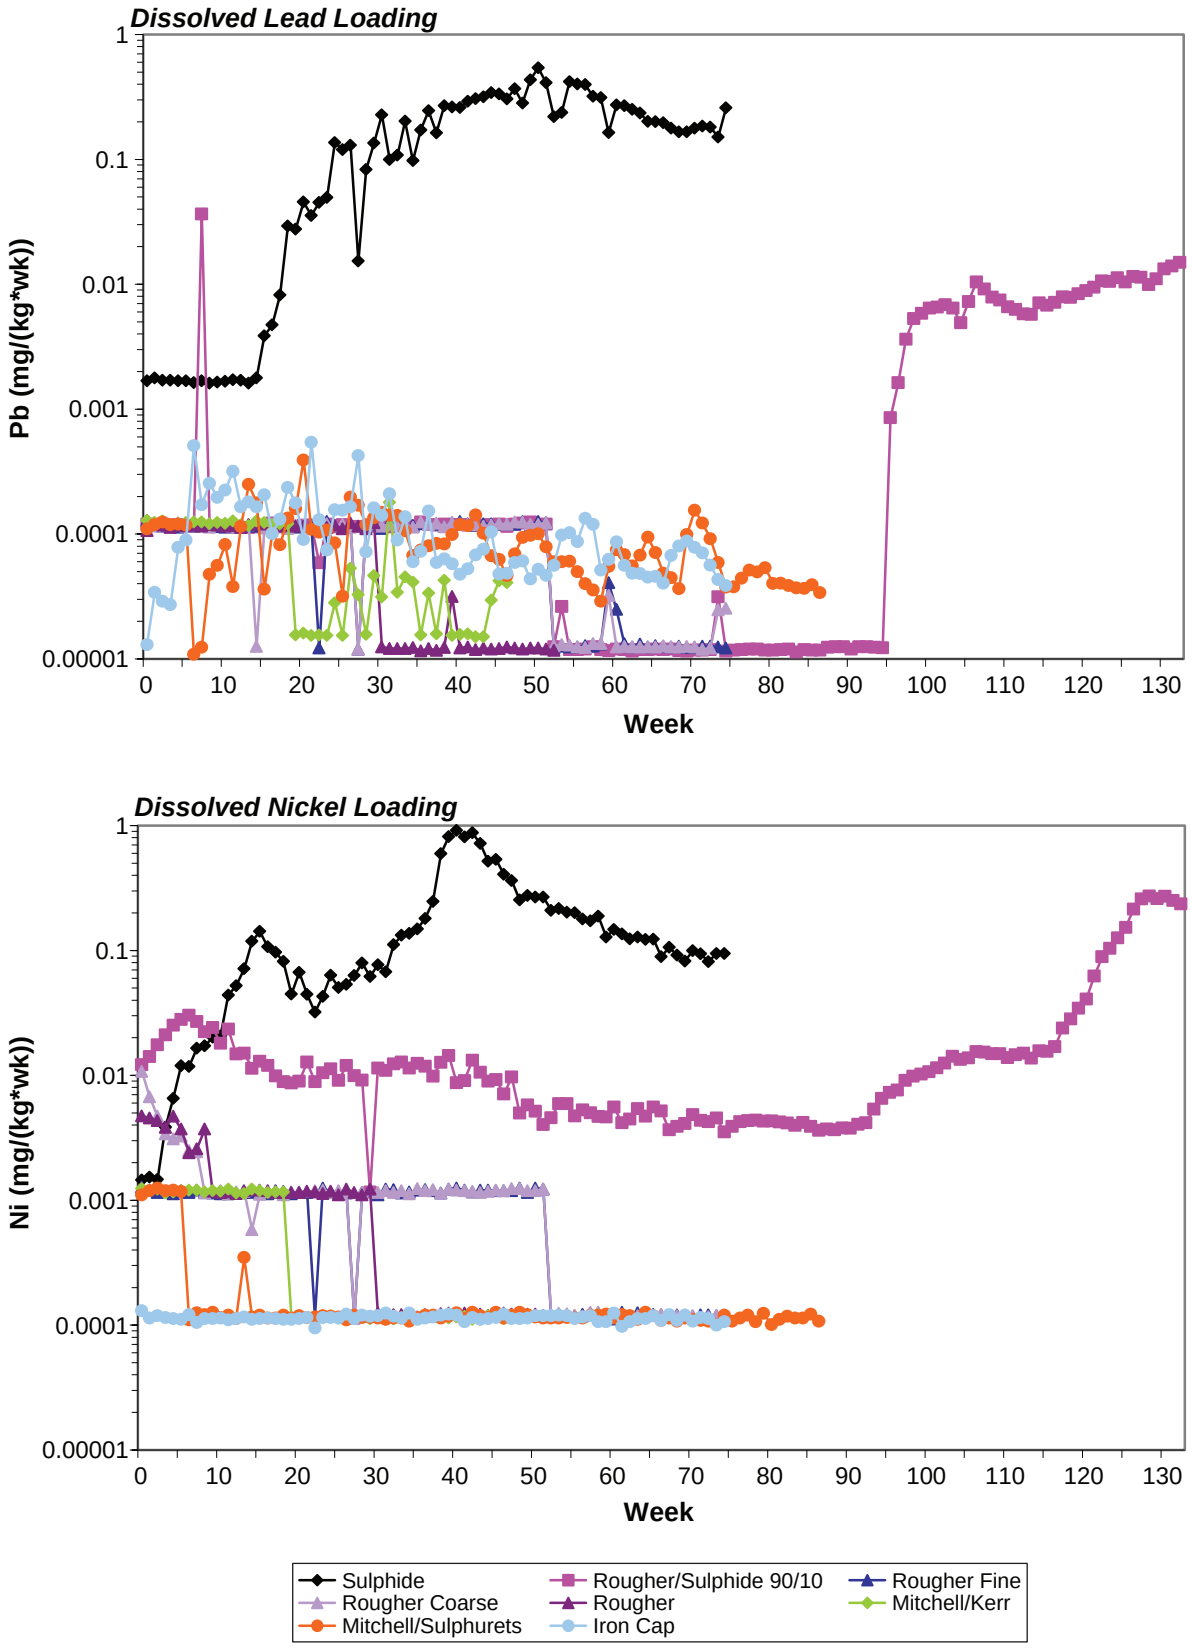
Lead concentrations in the near-neutral humidity cell leachates were frequently below detection. Lead leach rates sharply increased after week 12 in the Sulphide humidity cell, but began decreasing after week 54. Lead leach rates increased from below detection to 0.09 mg/kg/wk in the Rougher/Sulphide humidity cell between weeks 142 and 154 (Figure 6.2-8).

Nickel concentrations in the near-neutral humidity cell leachates were below the detection limit. Nickel leach rates in the Sulphide humidity cell increased to week 39 and subsequently decreased to 0.09 mg/kg/wk. Leach rates in the Rougher/Sulphide humidity cell ranged from 0.004 to 0.01 mg/kg/wk until week 110, when leach rates increased to 0.26 mg/kg/wk, and subsequently decreased (Figure 6.2-8).

Selenium leach rates decreased over time for most humidity cells. Leach rates in the last 10 weeks ranged from 0.001 to 0.002 mg/kg/wk, 0.0004 to 0.0005 mg/kg/wk, and 0.0008 to 0.0009 mg/kg/wk in the Sulphide, Mitchell/Kerr, and Iron Cap humidity cells, respectively (Figure 6.2-9).

Silver concentrations in the near-neutral humidity cells were below the detection limit. Silver leach rates increased after week 51 and 90 in the Sulphide and Rougher/Sulphide humidity cells, respectively (Figure 6.2-10).

Thallium concentrations were below the detection limit in the near-neutral humidity cells. Thallium leach rates in the Sulphide humidity cell ranged from 0.0003 to 0.0004 mg/kg/wk in the last 10 weeks. Thallium leach rates in the Rougher/Sulphide humidity cell increased after week 90 (Figure 6.2-10).



Vanadium concentrations were below the detection limit in the near-neutral humidity cells. Vanadium leach rates were highly variable, but increased over time in the Sulphide humidity cell to 0.012 mg/kg/wk. Vanadium leach rates increased in the Rougher/Sulphide cell after week 120 to 0.0022 mg/kg/wk (Figure 6.2-9).

Zinc concentrations were below the detection limit in the near-neutral humidity cells. Steady state zinc leach rates in the Sulphide humidity cell were 2.7 mg/kg/wk. Leach rates in the Rougher/Sulphide humidity cell were 0.03 mg/kg/wk after the increase at week 89, until a subsequent rate increase at week 110 to a maximum of 1.3 mg/kg/wk (Figure 6.2-11).

Table 6.2-1 summarizes the parameters with elevated concentrations from each tailing sample under acidic and neutral drainage conditions.

Elements Associated with the Neutralization Potential

Calcium leach rates decreased over time in all humidity cells. Steady state leach rates for the acidic Sulphide humidity cell and the near-neutral humidity cells ranged from 7 to 11 mg/kg/wk. Leach rates in the Rougher/Sulphide humidity cell decreased gradually to 35 mg/kg/wk to week 113, and subsequently decreased sharply to 5.25 mg/kg/wk. Magnesium leach rates increased over time in the acidic humidity cells. Steady state magnesium leach rates in the near-neutral humidity cells ranged from 0.5 to 1.5 mg/kg/wk (Figure 6.2-12).

n/a indicates that no humidity cell was observed.

6.2.1.3 Depletion Times and Onset of Acid Rock Drainage

The rates of depletion of sulphide, bulk Sobek NP, and carbonate NP were calculated and used to estimate the time to the onset of ARD and the time to the end of ARD for sub-aerial deposition of tailing. Table 6.2-2 presents a summary of these data by tailing type.

There is reasonable agreement in predictions of ARD onset based on the source of NP (bulk Sobek NP or carbonate NP). ARD onset is predicted to be quite rapid for Mitchell Sulphide and Mitchell Rougher/Sulphide tailing, but is predicted to never occur in the Mitchell Rougher-fine, Mitchell Rougher-coarse, Mitchell Rougher, Mitchell/Kerr Rougher, Mitchell/Sulphurets Rougher, or Iron Cap Rougher tailing.

6.2.2 Subaqueous Columns

The following discussion presents an assessment of porewater and supernatant analyses from the tailing subaqueous columns for:

- Indicators of acid generation (pH, sulphate, acidity, and alkalinity);
- Trace elements with elevated concentrations in the last 10 weekly cycles relative to water quality guidelines. Identification of these elements can be used to inform treatment design decisions and water quality modelling; and
- Calcium and magnesium which commonly occur in carbonate mineral phases and are associated with the neutralization potential.

The supernatant water from the tailing subaqueous columns is considered representative of the TMF cover water at the tailing solid-water interface and the porewater from the tailing subaqueous column is considered representative of the TMF tailing porewater.

The complete data set for subaqueous columns supernatant and pore water concentrations is presented in Appendix 6.2-3, and the graphs for additional parameters are presented in Appendix 6.2-4. Supernatant water was diluted at each sampling event during the kinetic tests and therefore leach rates could not be accurately calculated or evaluated. Decreasing concentrations over time may also reflect this dilution effect. Furthermore, the replaced supernatant water was not deoxygenated.

Table 6.2-2. Depletion Rates, Estimated Time to ARD Onset, and Estimated Time to End of ARD by Tailing Type for Humidity Cells

Cell ID	Adj SNPR	pH Last 10 Weeks	Sulphate Production Rate	Sulphide Depletion	Bulk NP Consumption Rate	Carbonate Depletion Rate	Bulk NP Depletion	Carbonate NP Depletion	ARD Onset (Bulk NP Depletion)	ARD Onset (Carbonate Depletion)	End of ARD (Bulk NP Depletion)	End of ARD (Carbonate Depletion)

Iron Cap	14.93	8.1	0.05	4	0.03	0.26	20740	5	never	never	n.a.	n.a.

Six subaqueous columns were operated for 48 to 129 weeks for the following tailing samples: Mitchell Sulphide, Mitchell Rougher/Sulphide, Mitchell Rougher, Mitchell/Kerr Rougher, Mitchell/Sulphurets Rougher, and Iron Cap Rougher. Both supernatant (TOP) and porewater (BOTTOM) data were collected.

6.2.2.1 pH, Sulphate, Acidity, and Alkalinity

The pH was higher in the porewater than in the supernatant for all subaqueous columns. The pH was typically near-neutral with the exception of alkaline pH (~11) in the porewater of the Mitchell/Sulphurets Rougher column, and acidic pH (<6.5) after week 40 in supernatant of the Mitchell Sulphide column and after week 64 in the supernatant of the Mitchell Rougher/Sulphide column. The pH stabilized in the supernatant of the Mitchell Sulphide column at approximately pH 3.75 at week 68, but the pH in the supernatant of the Mitchell Rougher/Sulphide decreased to pH 4.8 at 129 weeks (Figure 6.2-13).

Sulphate concentrations were typically orders of magnitude higher in the porewater than in the supernatant for an individual column. Sulphate concentrations initially decreased in both the supernatant and the porewater over a period of 6 to 30 weeks. Steady state sulphate concentrations in Iron Cap Rougher, Mitchell/Sulphurets Rougher, Mitchell/Kerr Rougher, and Mitchell Rougher supernatant ranged from 1 to 2 mg/L. Steady state sulphate concentrations in Mitchell Sulphide and Mitchell Rougher/Sulphide supernatant ranged from 28 to 80 mg/L (Figure 6.2-13).

Acidity was highly variable and frequently below detection in all subaqueous column samples. Acidity in the supernatant in Mitchell Sulphide tailing increased after week 56. Alkalinity was typically stable and comparable among supernatant and porewater samples of all columns, ranging from 20 to 50 mg $CaCO_3$/L. The exceptions were alkalinity values below detection in the acidic supernatants of the Mitchell Sulphide and Mitchell Rougher/Sulphide columns after weeks 42 and 69, respectively (Figure 6.2-14).

6.2.2.2 Trace Elements

Aluminum concentrations increased when supernatant waters became acidic in the Mitchell Sulphide and Mitchell Rougher/Sulphide columns. Aluminum concentrations also increased over time in the alkaline porewater of the Mitchell/Sulphurets Rougher column (Figure 6.2-15).

Antimony concentrations in Mitchell/Sulphurets Rougher, Mitchell Sulphide, and Iron Cap Rougher tailing porewater were comparable ranging from 0.01 to 0.02 mg/L. Antimony concentrations increased over time in the alkaline Mitchell/Sulphurets Rougher porewater. Concentrations below the detection limit were frequently observed in the Mitchell Rougher/Sulphide supernatant and porewater, the Rougher supernatant and porewater, and the Mitchell/Kerr Rougher supernatant (Figure 6.2-15).

Arsenic concentrations were elevated in the Iron Cap Rougher and Mitchell/Sulphurets Rougher porewater at 0.004 mg/L relative to the other columns. Arsenic concentrations decreased over time and were frequently below the detection limit in the other supernatant and porewater samples (Figure 6.2-16).

Cadmium concentrations were frequently below the detection limit in most columns. Cadmium concentrations were typically similar in the supernatant and porewater of an individual column, with the exception of the acidic supernatant of the Mitchell Sulphide column in which steady state cadmium concentrations were approximately 0.005 mg/L (Figure 6.2-16).

The Mitchell Sulphide column had steady state cobalt concentrations of 0.009 mg/L. The Mitchell Rougher/Sulphide column had steady state cobalt concentrations of 0.001 mg/L. Cobalt concentrations in the Mitchell/Kerr Rougher, Mitchell/Sulphurets Rougher, and Iron Cap Rougher supernatants and pore waters were frequently below detection (Figure 6.2-17).

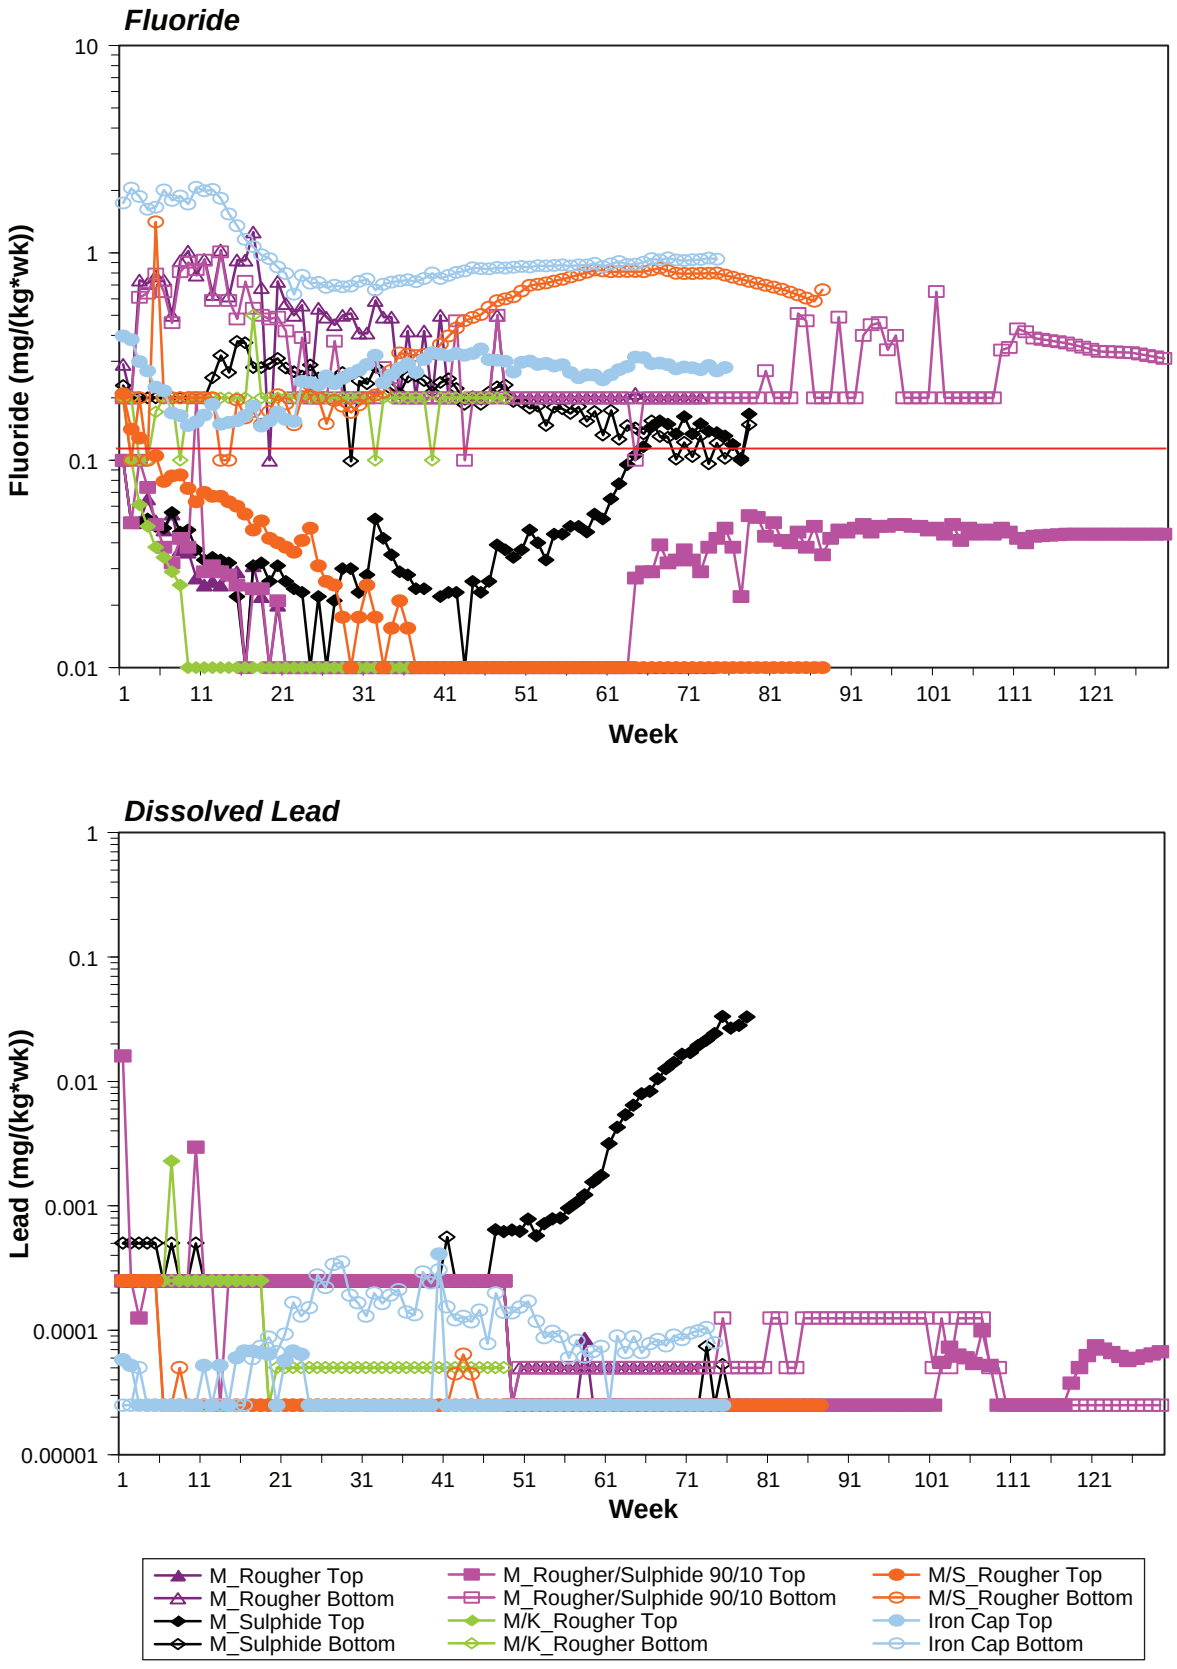
Copper concentrations decreased after week 42 in the Mitchell Sulphide column to 0.5 mg/L at week 76. Copper concentrations increased after week 53 in the Mitchell Rougher/Sulphide column when the pH became acidic to 0.24 mg/L at week 103. Copper concentrations were highly variable and/or frequently below detection in the other columns (Figure 6.2-17).

Fluoride concentrations were elevated in the porewater of the Mitchell Rougher/Sulphide and Iron Cap Rougher columns. Fluoride concentrations were frequently below detection in the other columns (Figure 6.2-18).

Lead concentrations increased over time in the supernatant of the Mitchell Sulphide column. Lead concentrations were below detection in all other columns and in the Mitchell Sulphide porewater (Figure 6.2-18).

Selenium concentrations were elevated at 0.015 mg/L in the Mitchell/Sulphurets Rougher porewater relative to the other columns. Selenium concentrations decreased over time in the Iron Cap Rougher supernatant and porewater, Mitchell/Sulphurets Rougher supernatant, Mitchell/Kerr Rougher supernatant and porewater, and Mitchell Sulphide supernatant and porewater (Figure 6.2-19).



Zinc concentrations in the Mitchell Sulphide and Mitchell Rougher/Sulphide columns were stable at 0.2 and 0.02 mg/L, respectively. Concentrations of the supernatant and porewater of the Micthell Rougher, Mitchell/Kerr Rougher, Mitchell/Sulphurets Rougher, and Iron Cap Rougher columns were frequently below the detection limit (Figure 6.2-19).

Table 6.2-3 summarizes the parameters with elevated concentrations in each tailing subaqueous column.

6.2.2.3 Elements Associated with the Neutralization Potential

Calcium concentrations were typically one to two orders of magnitude higher in the porewater than the supernatant of an individual column. Calcium concentrations generally decreased over time but were greatest in Mitchell Sulphide and Mitchell Rougher/Sulphide and lowest in Mitchell/Sulphurets Rougher, Mitchell/Kerr Rougher, Mitchell Rougher, and Iron Cap Rougher. Magnesium concentrations were between 0.5 and 4 mg/L in all columns with the exception of the porewater of the alkaline Mitchell/Sulphurets Rougher column which had very low magnesium concentrations (Figure 6.2-20).

6.2.3 Aging Tests

The following discussion presents an assessment of the supernatant analyses from the tailing aging tests for:

- Indicators of acid generation (pH, sulphate, acidity, and alkalinity);
- Cyanide and nutrients;
- Trace elements with elevated concentrations in the last 10 weekly cycles relative to water quality guidelines. Identification of these elements can be used to inform treatment design decisions and water quality modelling; and
- Calcium and magnesium which commonly occur in carbonate mineral phases and are associated with the neutralization potential.

The supernatant water from the aging columns is considered representative of the TMF cover water without considering additional water inputs.

The complete data set for aging tests supernatant concentrations is presented in Appendix 6.2-5 and the graphs for additional parameters are presented in Appendix 6.2-6. Supernatant water was removed and not replaced at each sampling event during the kinetic tests and therefore leach rates could not be accurately calculated or evaluated. Increasing concentrations over time may reflect a small load or flux from the tailing material into a decreasing volume of water.

The following discussion relates to three aging test that were operated for 30 to 120 days for the following Mitchell tailing samples: Sulphide, Rougher/Sulphide, and Rougher. Given the size and proposed life of the Mitchell deposit, Mitchell tailing chemistry is expected to dominate the chemistry of the TMF.

6.2.3.1 pH, Sulphate, Acidity, and Alkalinity

The pH in all three aging tests was near-neutral to weakly alkaline throughout the test. Between days 60 and 120, the pH in the Rougher/Sulphide aging test decreased from 8.1 to 6.9, while the pH in the Rougher and Sulphide aging tests remained stable (Figure 6.2-21).

Sulphate concentrations steadily increased over 30 to 120 days, indicating sulphide oxidation was occurring. The sulphate concentration in the Sulphide aging test doubled over 120 days (Figure 6.2-21).

Acidity generally increased over 120 days in the Rougher/Sulphide and Sulphide aging tests. Acidity decreased over 30 days in the Rougher aging test. Alkalinity increased from day 0 to day 14 in the Rougher/Sulphide aging test and subsequently decreased. Alkalinity increased for 30 days in the Rougher aging test, and was relatively stable over 120 days in the Sulphide aging test (Figure 6.2-22).

6.2.3.2 Elements that Contribute to Acidity

Aluminum concentrations were highly variable over time and were occasionally below detection in the Rougher/Sulphide and Rougher supernatants. Dissolved aluminum was frequently below detection in the Rougher/Sulphide and Rougher aging tests, and decreased in concentration over time in the Sulphide aging test (Figure 6.2-23).

Iron concentrations in the Rougher/Sulphide and Rougher supernatants were highly variable. The total iron concentration in the Sulphide supernatant gradually decreased over 120 days. Dissolved iron concentrations in the Sulphide aging test represented close to 100% of the total iron concentration. Dissolved iron concentrations in the Rougher/Sulphide supernatant decreased to below the detection limit at 90 days, and concentrations in the Rougher supernatant were always below detection (Figure 6.2-24).

Manganese concentrations increased over time in all three tests, but were variable in the Sulphide supernatant (Figure 6.2-25).

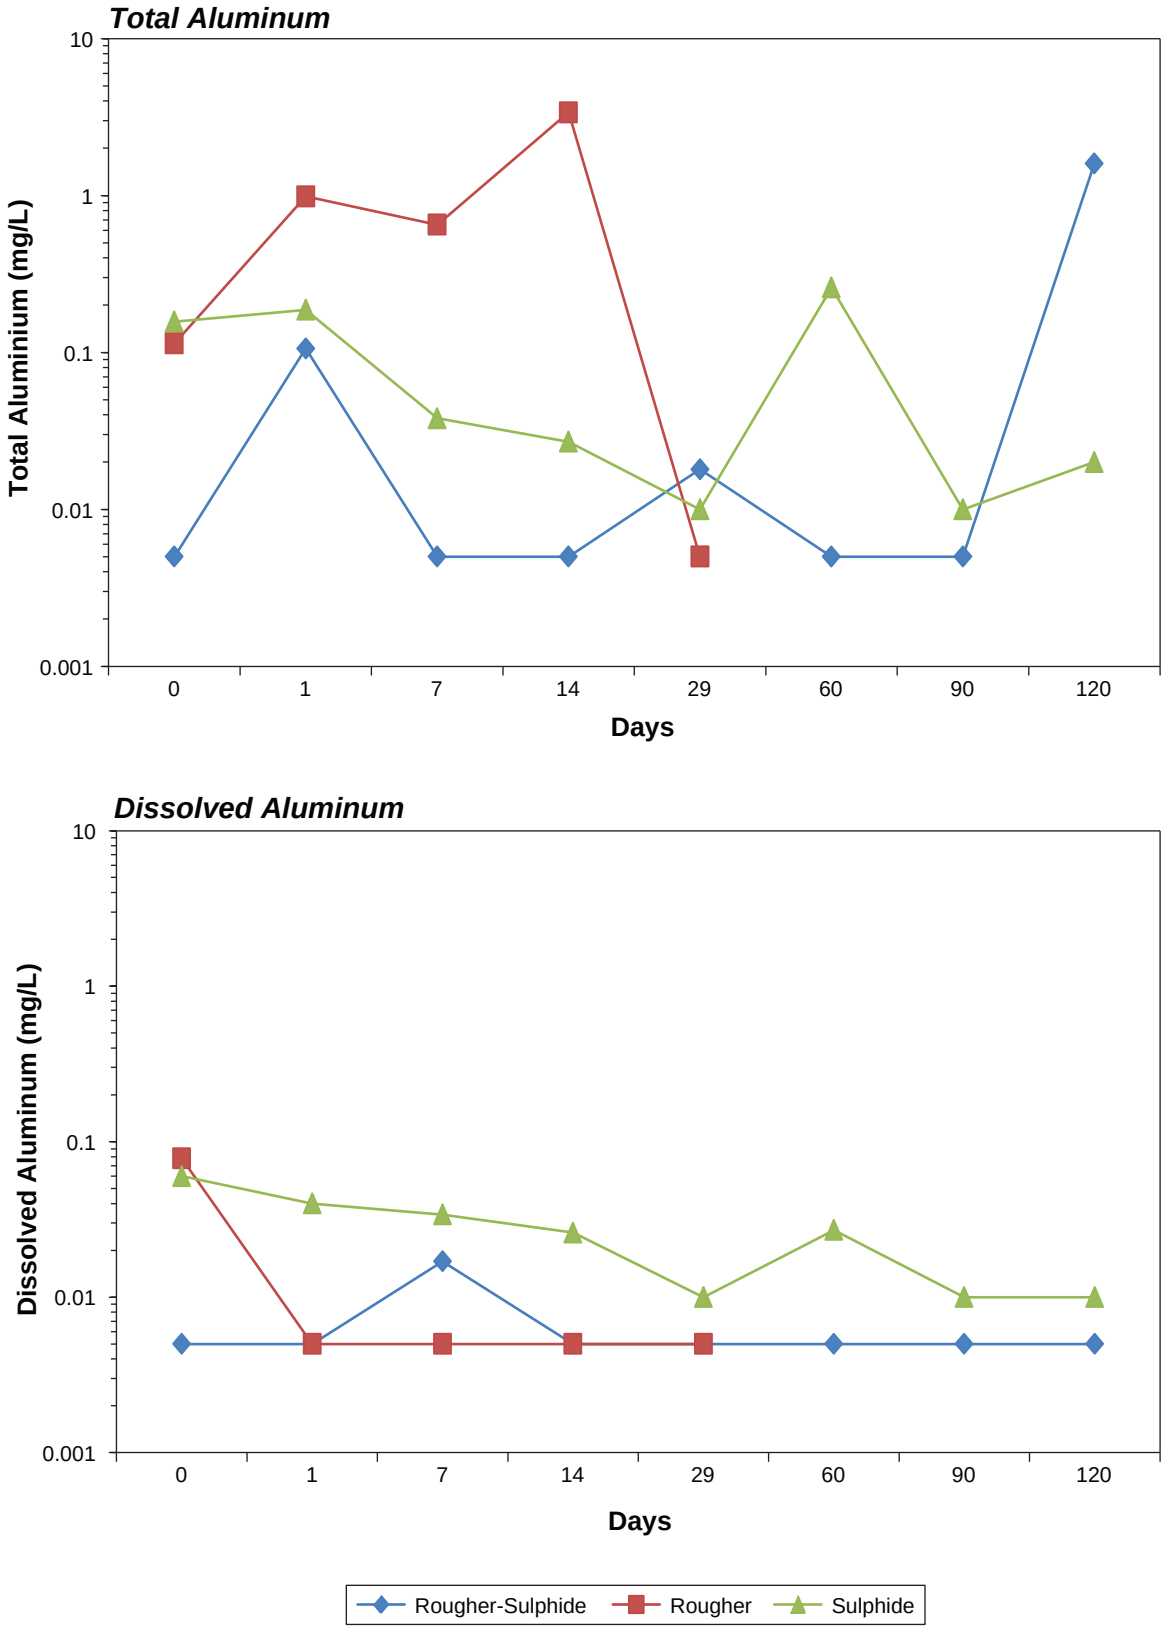
6.2.3.3 Cyanide and Nutrients

Weak acid dissociable (WAD) cyanide was not measured in the Rougher aging test because cyanide is not used as a reagent in the flotation process that produces the Rougher tailing. WAD cyanide concentrations decreased 120 days in both the Rougher/Sulphide and Sulphide aging test (Figure 6.2-25).

Ammonia concentrations decreased over time in the Rougher and Sulphide supernatants, with final concentrations of below detection and 50 mg/L respectively. Ammonia concentrations increased over time in the Rougher/Sulphide aging test to 23 mg/L (Figure 6.2-26).

Total phosphate concentrations decreased over 30 days in the Sulphide aging tests. In the Rougher aging test, concentrations were highly variable over 30 days. Concentrations were relatively constant at approximately 0.25 mg/L in the Rougher/Sulphide aging test (Figure 6.2-26).

6.2.3.4 Trace Elements



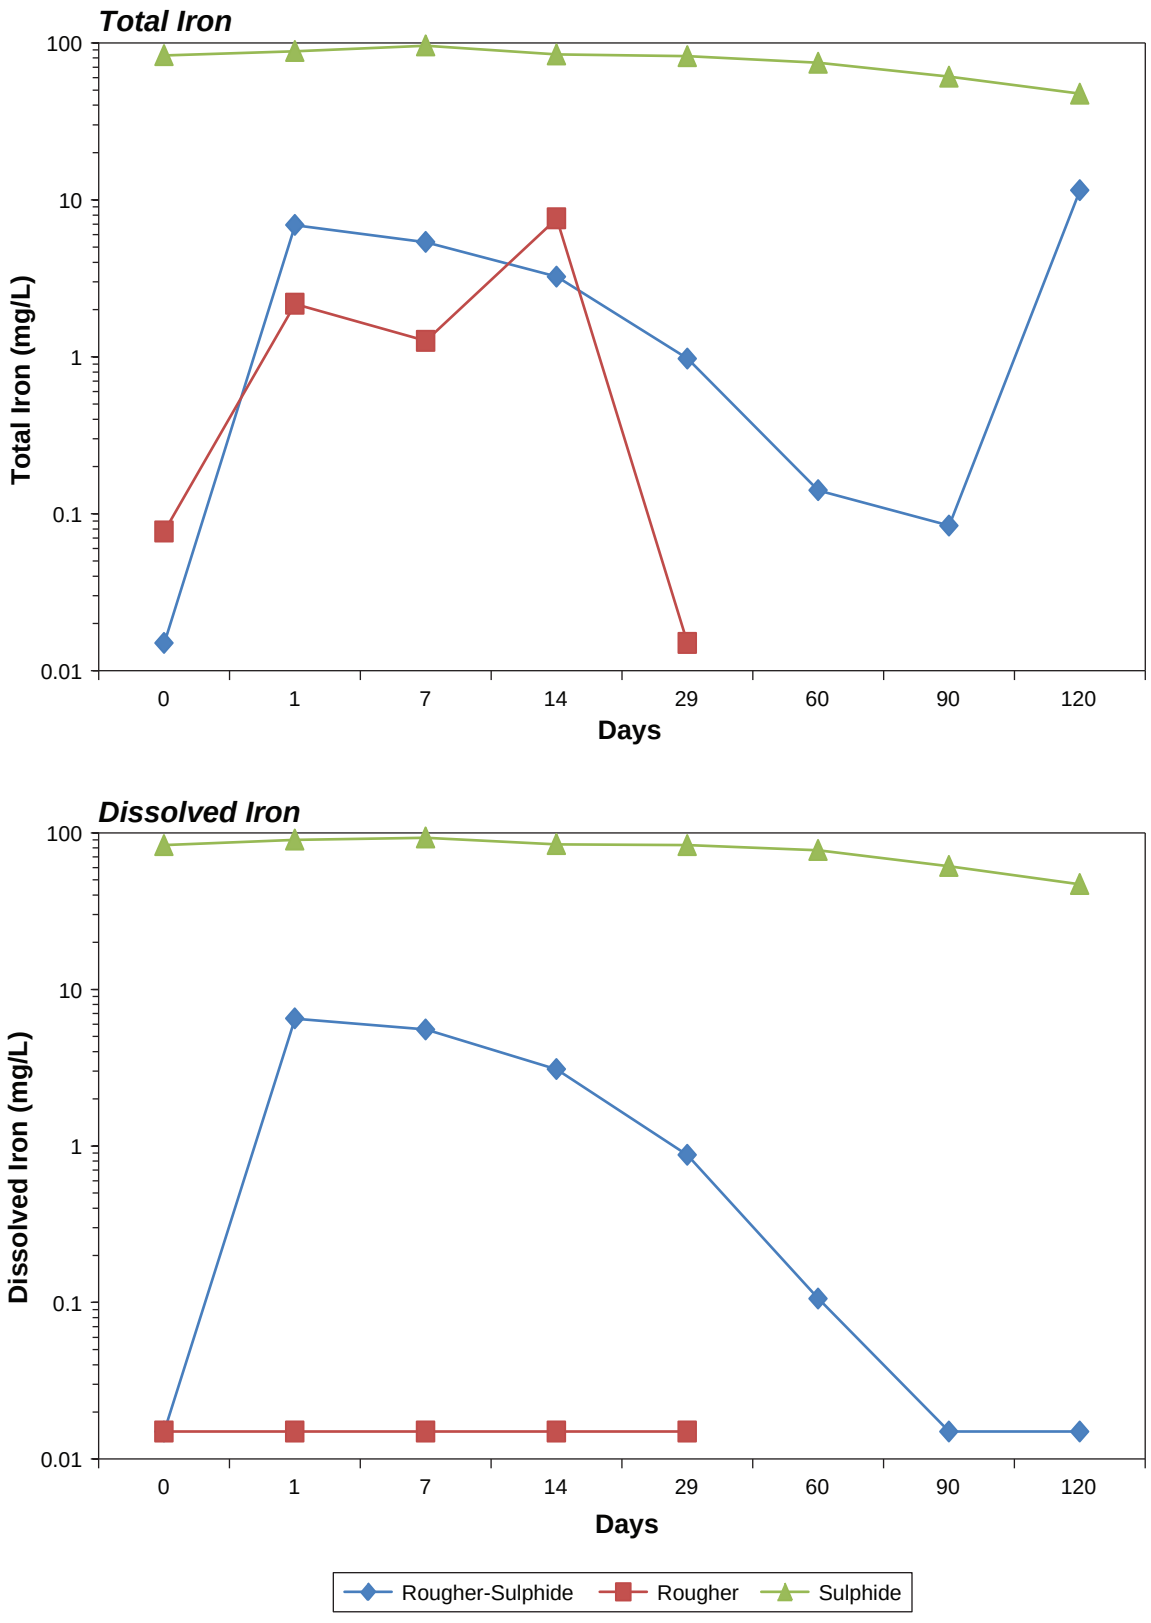
Trace element concentrations were generally greatest in the Sulphide supernatant and lowest in the Rougher supernatant.

Antimony concentrations generally decreased over time in the Sulphide and Rougher/Sulphide aging tests. Concentrations in the Rougher supernatant were always below the detection limit (Figure 6.2-27).

Total arsenic concentrations were elevated in the Sulphide aging test for the first 14 days and subsequently were below the detection limit. Arsenic concentrations in the Rougher/Sulphide aging test were frequently below detection but increased at day 120 to 0.0058 mg/L. Rougher supernatant arsenic concentrations were frequently below the detection limit (Figure 6.2-27). Note that detection limits for arsenic varied among tailing aging tests.

Cadmium concentrations increased over time in the Rougher/Sulphide supernatant. Cadmium concentrations were variable in the Sulphide and Rougher supernatant, ranging from 0.00017 to 0.0016 mg/L and below detection to 0.0002 mg/L respectively (Figure 6.2-28).

Cobalt concentrations increased slightly over time in the Sulphide and Rougher/Sulphide aging tests, while concentrations in the Rougher supernatant were always below detection (Figure 6.2-28).



Note: Values below the detection limit are plotted as half the detection limit.

Copper concentrations increased over time in the Rougher/Sulphide supernatant and decreased over time in the Sulphide supernatant with the exception of an increase in the last 30 days. Concentrations in the Rougher supernatant were variable over time at 30 days were one to two orders of magnitude lower than the other two aging tests (Figure 6.2-29).

Fluoride concentrations increased over time all three aging tests to between 0.4 to 1.0 mg/L (Figure 6.2-29).

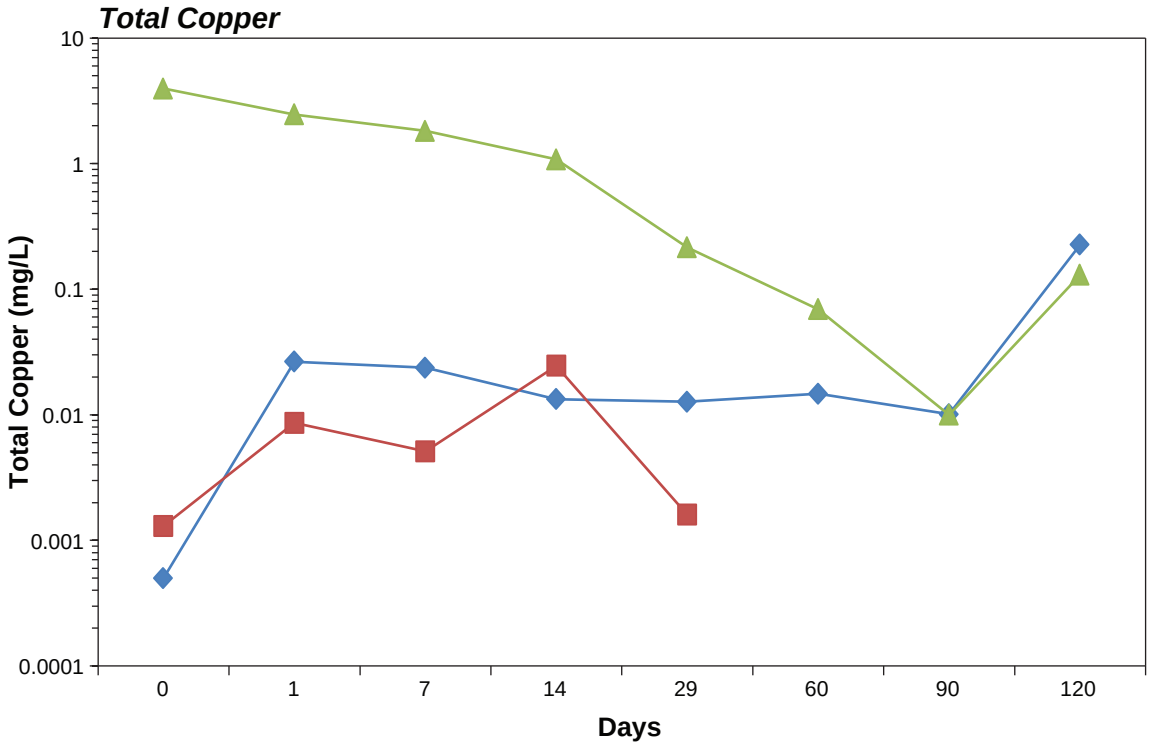
Mercury concentrations were always below the detection limit in the Rougher supernatant. Concentrations in the Rougher/Sulphide and the Sulphide supernatants followed a similar pattern of variability with concentrations at 120 days ranging from 0.000018 to 0.00015 mg/L (Figure 6.2-30).

Molybdenum concentrations were generally stable over time at approximately 0.2 mg/L in the Sulphide supernatant with the exception of an outlier low concentration at day 90. Molybdenum concentrations in the Rougher/Sulphide and the Rougher supernatants were approximately an order of magnitude lower (Figure 6.2-30).

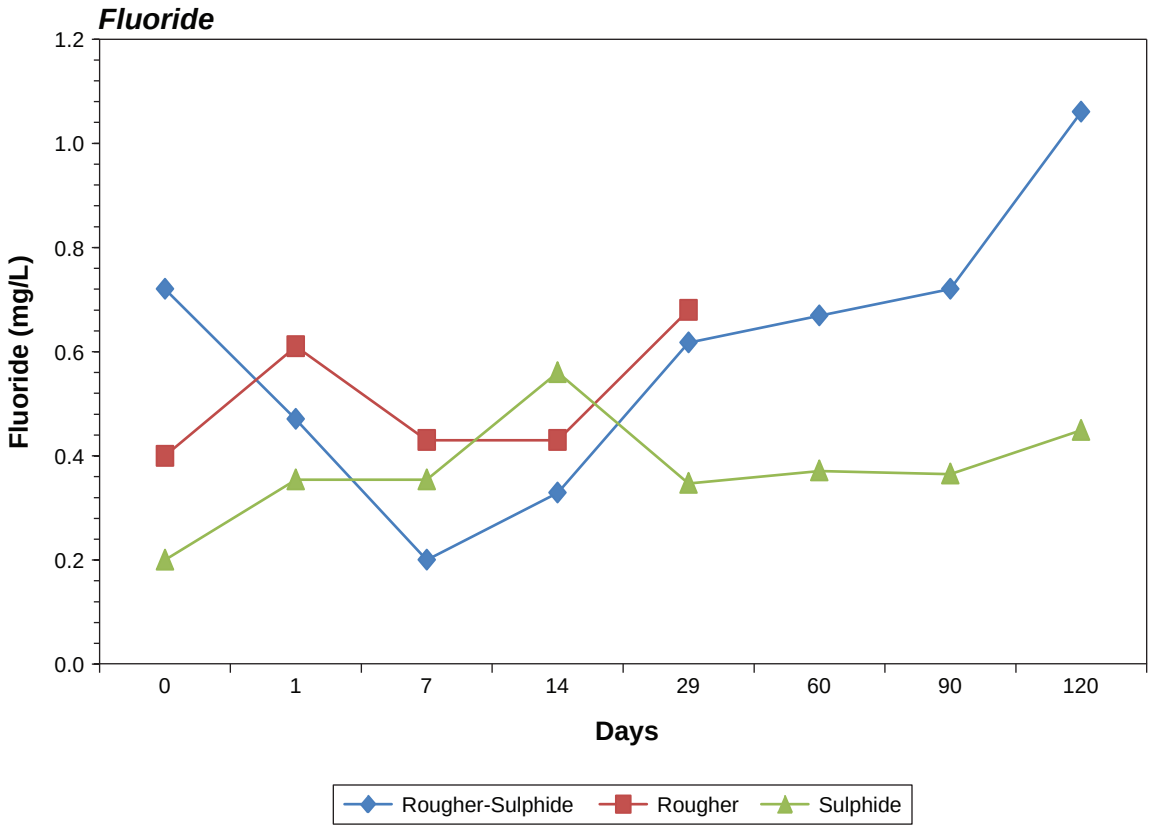
Selenium concentrations decreased over time in the Rougher/Sulphide and the Sulphide supernatants to final concentrations of 0.004 and 0.02 mg/L respectively. Selenium concentrations in the Rougher supernatant decreased to day 7 and then increased to day 30 to 0.003 mg/L (Figure 6.2-31).

Silver concentrations increased over time to 0.0009 mg/L in the Rougher/Sulphide supernatant. Concentrations were relatively stable in the Sulphide supernatant at 0.006 mg/L and were frequently below detection in the Rougher supernatant (Figure 6.2-31).

6.2.3.5 Elements Associated with the Neutralization Potential



Calcium concentrations were generally stable in the Rougher and Rougher/Sulphide aging tests at approximately 650 mg/L. Calcium concentrations increased over time to 350 mg/L in the Sulphide supernatant.



Magnesium concentrations increased over time in all three aging tests with final concentrations ranging from 14 to 24 mg/L.

6.2.4 Comparison between Subaqueous Columns and Aging Tests: Mitchell Deposit

The supernatant concentrations of both the subaqueous columns and the aging tests are expected to represent the concentrations in the cover water in the TMF. The same Mitchell tailing samples (Rougher/Sulphide; Rougher; Sulphide) were evaluated in both kinetic tests permitting a comparison.

In general, this comparison indicates that the concentrations of trace elements in the supernatant were dependent on the pH. In the subaqueous column and aging test for the Rougher tailing sample the supernatant pH was comparable and most parameters were similar in concentration. In contrast, for the Rougher/Sulphide and Sulphide tailing samples, the pH of the supernatant was acidic in the subaqueous columns and near-neutral to weakly alkaline in the aging tests. For those tailing samples, the trace element behaviour followed predictable pH patterns. In the acidic subaqueous column supernatants, higher concentrations of aluminum, cadmium, copper, lead, and zinc were observed which is consistent with acidic metal leaching for those elements. It is important to note that oxygenated water was replaced each week in the subaqueous columns and therefore oxygen concentrations in the supernatant were likely significantly higher in the subaqueous columns than in the aging tests. In the near-neutral aging test supernatants, higher concentrations of antimony, fluoride, molybdenum, and selenium likely reflected neutral metal leaching which is expected with those elements.

6.3 SUMMARY: TAILING

Table 6.3-1 summarizes the water quality parameters with elevated concentrations in the three tailing kinetic tests: humidity cells, subaqueous columns, and aging tests. Metal leaching typically reflected the pH of the water and there was generally good agreement across tests. Aluminum, arsenic, fluoride, cadmium, copper, selenium, sulphate, and zinc were most frequently elevated across various tailing types and across a range of pH conditions.

Table 6.3-1. Tailing Metal Leaching Summary

7. Non-Deposit Rock Results

This section describes the geochemical characteristics of the KSM non-deposit material and its potential for ML/ARD based on the geochemical static test results. This section of the report incorporates results collected up till the end of July 2012.

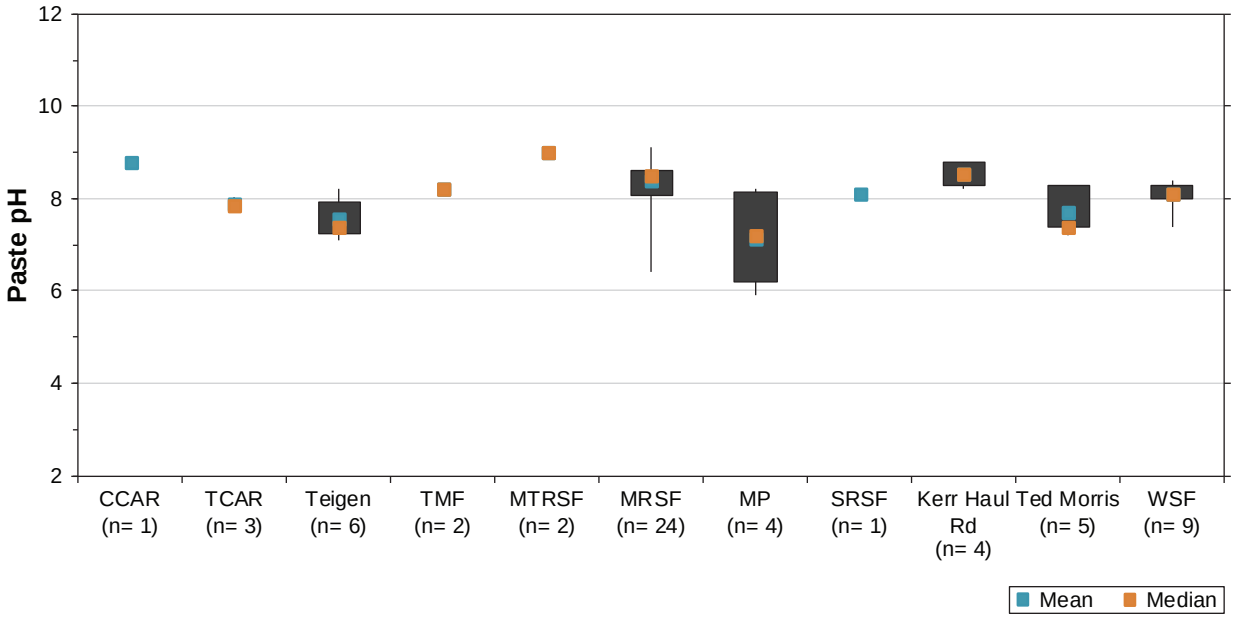
Non-deposit material assessed for this characterization includes overburden samples collected from drill holes and grab samples from hand-dug test pits and rock samples collected from drill holes and grab samples hammered from outcrops. Table 4.1-2 summarises the sampling program, dividing the samples collected by location and type. Results of the static testing for non-deposit samples can be found in Appendix 7-1 and 7-2.

7.1 OVERBURDEN STATIC TESTS

Non-deposit overburden material is likely to be used for reclamation and as fill material for construction of buildings and roads. As such it will likely be moved during the life of the operation and remain exposed to physical and chemical weathering and erosion conditions similar to those to which the material is currently being exposed. Overburden material had significant variability based on the sampling site; from organic silts to well graded, fine to coarse gravels.

Particle size distribution curves for each of the overburden grab samples are provided in Appendix 7.1-1. The particle size distributions indicate that the majority (~75%) of these overburden samples were comprised of a mixture of fine to coarse gravels and fine to coarse sands with lesser (<20%) amounts of silt and clay particles typical of glacial tills. A minor proportion of the tested samples (~5%) were dominantly fines (clay or silt) including samples WP09-37 and WP09-53B from MRSF overburden, and samples WP09-56, WP09-56A, and WP09-57 from WSF overburden .

7.1.1 Paste pH



The paste pH values for non-deposit overburden material vary between 5.9 and 9.1, with the largest interquartile range ascribed to Mitchell Pit samples (Figure 7.1-1). Mean and median values of all 63 samples were above 6.0 indicating that the majority samples were not acid generating at the time of sample collection. The only sample with an acidic paste pH was morainal silty clay from within the outline of the proposed Mitchell Pit.

7.1.2 Sulphur Species

The total-sulphur in the non-deposit overburden samples varied over two orders of magnitude (Figure 7.1-2) with the lowest value (0.005%) at the MRSF and the highest (6.78%) from the Mitchell Pit. Median values varied between 0.04 and 1.22%.

The sulphide-sulphur in the non-deposit overburden samples has a similar range to the total-sulphur (Figure 7.1-2 and 7.1-3) and is the dominant sulphur species.

The highest sulphate-sulphur concentration was 0.31% from a sample of clayey sand in the Mitchell Pit (Figure 7.1-2 and 7.1-3); sulphate-sulphur concentrations were frequently below method detection limits (0.01%).

KSM PROJECT

Non-Deposit Overburden Statistical Summary of Bulk Neutralization Potential Values and Paste pH versus Bulk Neutralization Potential Values by Location

Figure 7.1-3

Rescan™ Engineers & Scientists

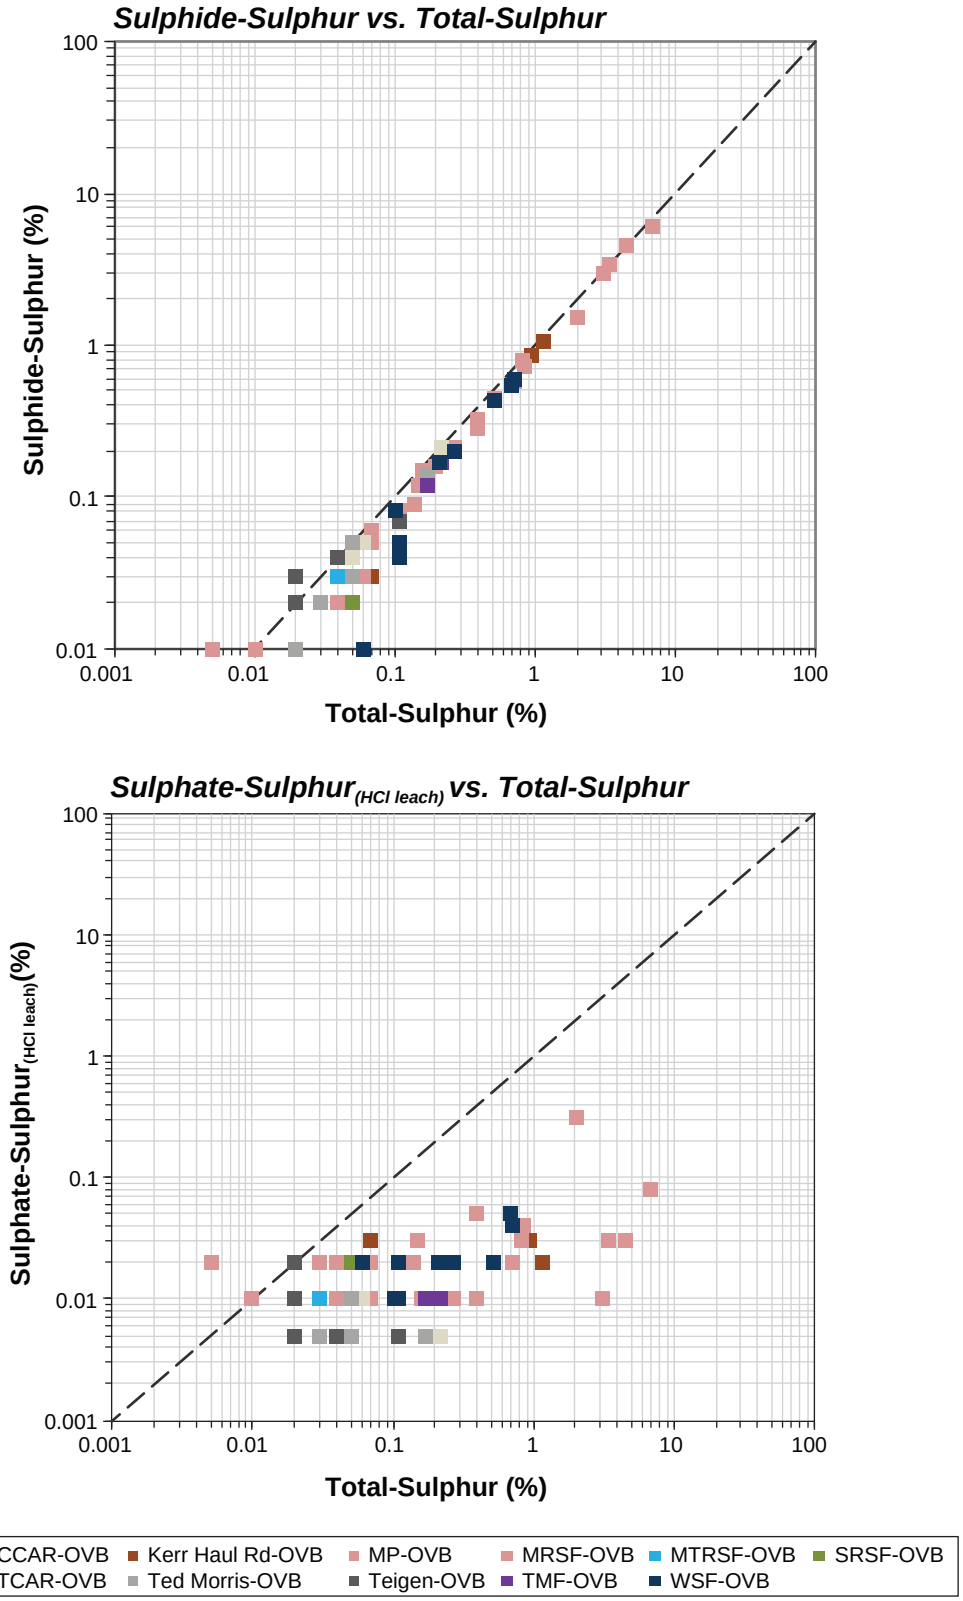
7.1.3 Neutralization Potential

The bulk NP values for non-deposit overburden are summarized in Figure 7.1-4. Bulk NP values are generated by the bulk Sobek method and represent easily accessible and some unavailable NP. Bulk Sobek NP values for non-deposit overburden vary between 6 and 304 kg $CaCO_3$/t. Teigen Access Road (not currently part of the mine plan), Mitchell Pit, and SRSF samples have slightly lower bulk Sobek NP values than the other locations. The only sample with a paste pH below 6.0 had a bulk Sobek NP value of 9 kg $CaCO_3$/t. This bulk Sobek NP value could be applied as a site-specific unavailable NP as the sample is already acid generating. However, the sample is silty moraine from within the outline of the proposed Mitchell Pit. It is likely that this glacial moraine material includes from ground up rock from the Mitchell, Snowfields, or Iron Cap deposits. All these deposits have a large amount of PAG material and therefore any moraine generated from those sources will have a high probability of being PAG. As a result a site-wide unavailable NP value will not be used for the overburden material. Caution should be used when generating SNPR values for morainal material as the bulk NP may not be completely available.

The Inorg NP, derived from inorganic carbon values, typically underestimates the NP of samples when compared to the bulk Sobek NP (Figure 7.1-5). Conversely, the Ca CaNP, derived from calcium concentrations, typically overestimates the NP of the samples when compared to the bulk Sobek NP. The CaMg CaNP does not correlate well with bulk Sobek NP indicating that the magnesium occurs in non-carbonate magnesium-bearing mineral phases.

7.1.4 Sulphide Net Potential Ratios

The SNPR values discussed below are unadjusted SNPR values based on the unadjusted NP for non-deposit overburden as there was no unavailable NP. The only location that had a large proportion of samples with a SNPR value less than 2.0 was the Mitchell Pit (Figure 7.1-6). Mean and median SNPR values were consistently above 4.0 for the other non-deposit overburden sampling locations indicating very low potential for acid generation.



The Teigen Creek Valley overburden samples plotted in a slightly different trend compared to the other sample locations (Figure 7.1-7). These samples plot on a fairly straight line in both graphs, in contrast to the other sample datasets. This may be due to low sulphide-sulphur and low bulk NP values in these samples.

7.1.5 Whole Rock and Solid-phase Elemental Analysis

Results of the whole rock XRF and four acid digestion followed by ICP-MS and the summary statistics can be found in Appendix 7-1.

7.2 ROCK STATIC TESTS

Non-deposit rock material is likely to be exposed during road construction or in locations where bedrock will be blasted to make level surfaces, e.g. building or dam foundations, or used as fill material during construction of buildings and potentially in roads. As such it will likely be moved during the life of the operations and remain exposed to physical and chemical weathering and erosion conditions different to that to which the material is currently being exposed. The 192 rock samples vary between sedimentary and volcanic rock types and come from the Stuhini, Hazelton, Bowser Lake Groups, and one sample from the Zippa Mountain Plutonic Complex.

Figure 7.1-7

Rescan™ Engineers & Scientists

7.2.1 Paste pH

The paste pH interquartile range for most sample locations is around 4.5 to 9.4 (Figure 7.2-1). Median pH values ranged from 7.3 to 8.9. One location have 25th percentile values below 6.0: Mitchell Pit (5.9). The mean and median values at each location are greater than 7.0 indicating that the majority of materials in these locations have enough NP to not be immediately acid generating.

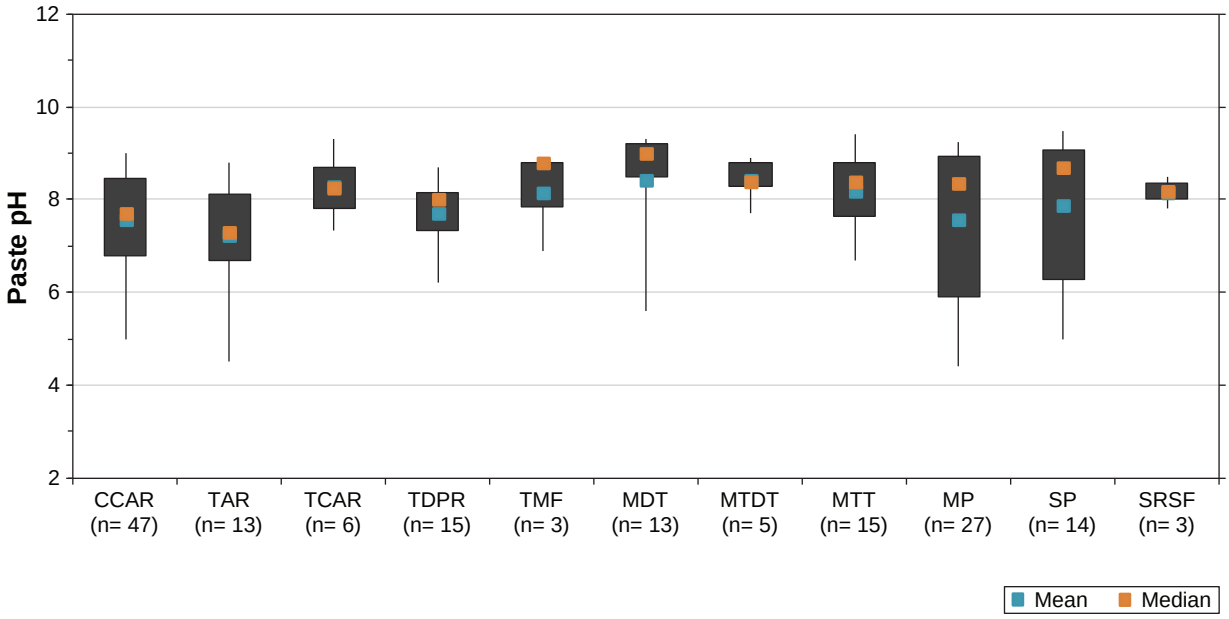
7.2.2 Sulphur Species

Locations with mean and median total-sulphur values greater than or equal to 0.3% are: MDT, Mitchell Pit, Sulphurets Pit, and Sulphurets Laydown Area (Figure 7.2-2). Samples collected from the vicinity of the four access roads that have been proposed at various times between 2008 and 2012 and the TMF have low total-sulphur values, with median and mean values less than 0.3%. The six MTDT samples were tightly clustered between 0.05% and 0.13 total-sulphur, while the MTT had a skewed dataset with a median at 0.07% and a mean at 0.30% total-sulphur.

Sulphide-sulphur values are very similar to total-sulphur values (Figure 7.2-2 and 7.2-3) and are the dominant sulphur species in the non-deposit rock samples. Sulphate-sulphur is the minor sulphur species (Figure 7.2-2 and 7.2-3).

7.2.3 Neutralization Potential

The bulk Sobek NP value for non-deposit rock material can vary significantly by location and within a location (Figure 7.2-4). The TAR dataset was the only location to have a median bulk Sobek NP less than 10 kg $CaCO_3$/t. The spread in the values at CCAR, Mitchell Pit, and Sulphurets Pit is quite large: from less than 1 kg $CaCO_3$/t to more than 100 kg $CaCO_3$/t. Typically other locations had bulk Sobek NP values between 5 and 70 kg $CaCO_3$/t. The three Sulphurets Laydown Area samples were tightly clustered between 84 and 125 kg $CaCO_3$/t.



Compared to the bulk Sobek NP the Inorg NP and Ca CaNP values are similar with some scatter around the 1:1 correlation line (Figure 7.2-5). This trend indicates that inorganic calcium carbonate is the main source of NP in the samples.

The CaMg CaNP does not correlate well with bulk Sobek NP indicating that the magnesium occurs in non-carbonate magnesium-bearing mineral phases.

Samples from the CCAR, MDT, Mitchell Pit, and Sulphurets Pit had paste pH values less than 6.0. This indicates that the bulk Sobek NP was insufficient to neutralize the acid produced and this NP is unavailable. The highest NP with a paste pH less than 6.0 was 9 kg $CaCO_3$/t from a MDT sample. The access road samples are discussed in detail in (Rescan 2012b) and the effect of unavailable NP is taken into consideration.

7.2.4 Sulphide Net Potential Ratios

The SNPR can be calculated with either unadjusted bulk Sobek NP, or as an adjusted SNPR which is calculated from the adjusted bulk Sobek NP. The unavailable NP ascribed to the adjusted SNPR values is outlined in Table 7.2-1. Access road values are taken from the KSM Project: Access Roads Metal Leaching and Acid Rock Drainage Potential Assessment (Rescan 2012b) values of 15 are used for material collected within the mine area and close to mine waste rock, and the PTMA is assigned a value of 8 kg $CaCO_3$/t due to the TDPR dataset.

Figure 7.2-5

Rescan™ Engineers & Scientists

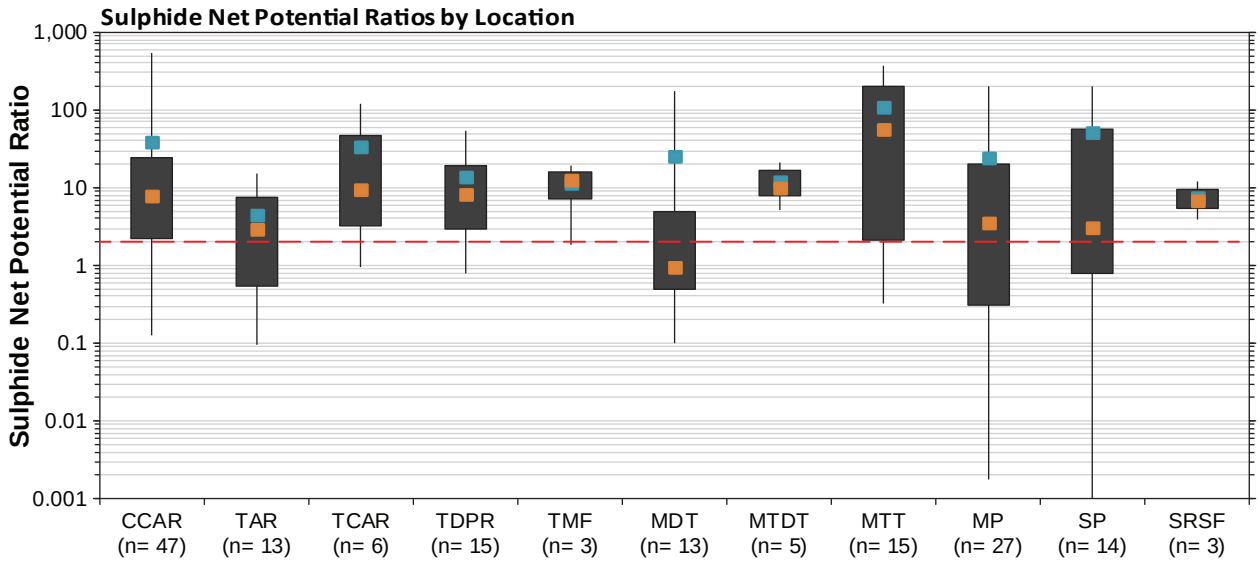
Table 7.2-1. Unavailable Sobek Bulk Neutralization Potential Used In Adjusted Sulphide Net Potential Ratios

Location	Unavailable NP (kg $CaCO_3$/t)	Location	Unavailable NP (kg $CaCO_3$/t)
CCAR	9	Sulphurets Pit	15
MDT	15	Sulphurets Laydown Area	0
Mitchell Pit	15	TAR	8
MRSF	0	TCAR	0
MTDT	0	TDPR	8
MTRSF	0	PTMA	8
MTT	0		

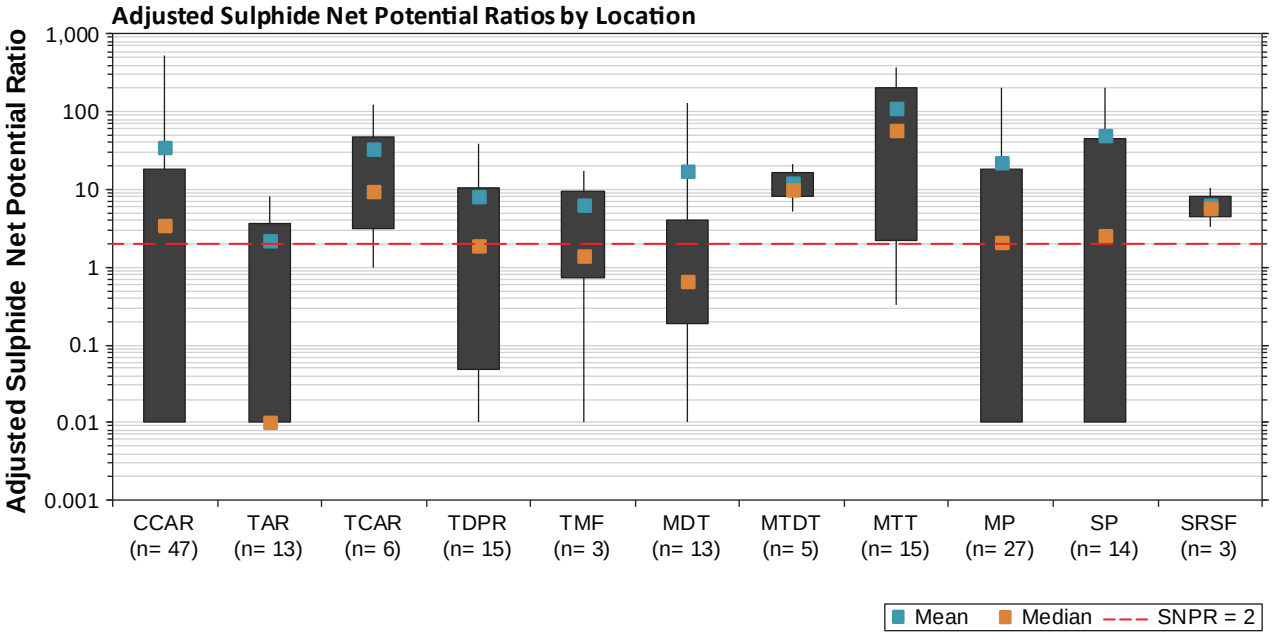
The TAR, MDT, Mitchell Pit, and Sulphurets Pit have at least 25% of samples with a SNPR less than 2.0 (Figure 7.2-6), indicating that this material will become acid generating at some point. After taking into account the unavailable NP the CCAR, TDPR, and PTMA datasets have more than 25% of samples with an adjusted SNPR less than 2.0 (Figure 7.2-6). The only locations that have a low potential for acid generation are: TCAR, MTDT, and Sulphurets Laydown Area. However, these locations also have the lowest number of samples collected.

7.2.5 Whole Rock and Solid-phase Elemental Analysis

Results of the whole rock XRF and four acid digestion followed by ICP-MS and the summary statistics can be found in Appendix 7.1.



7.3 LEACHATE TESTS



7.3.1 Overburden Shake Flask Extraction

Four overburden samples were subjected to a 24 hour shake flask extraction: two from the Mitchell Pit and two from MRSF. The full table of analyses is presented in Appendix 7.3-1.

7.3.2 Rock Meteoric Water Mobility Protocol

Three composites were created to test the mobility of elements from Mitchell highwall material. The full results and additional figures can be found in Appendix 7.3-2 and appendix 7.3-3, respectively. As the MWMP progressed the loadings increased fairly consistently, although Cycle 3 was sometimes lower than Cycle 2 and 4.

8. Groundwater Seep Results

Naturally-occurring groundwater seeps were sampled for water quality parameters at the Kerr, Sulphurets, and Mitchell Deposits, and in the McTagg and Ted Morris Creek Valleys in 2009, 2010, and 2012. The complete water quality data for the deposit seeps are presented in Appendix 8.1-1 and the dataset for the McTagg and Ted Morris Creek Valleys is presented in Appendix 8.1-2.

8.1 SEEP GEOCHEMISTRY

The following discussion presents an assessment of the water quality analyses from the groundwater seeps for:

- Indicators of acid generation (pH, sulphate, acidity, and alkalinity);
- Elements that contribute to acidity (aluminum, iron, and manganese);
- Barium which is most commonly associated with barite ($BaSO_4$), a highly insoluble mineral;
- Trace elements with elevated concentrations relative to water quality guidelines. Identification of these elements can be used to inform upper limits on water quality modelling; and
- Calcium and magnesium which commonly occur in carbonate mineral phases and are associated with the neutralization potential.

The deposit seeps were characterized by deposit and/or degree of alteration at the discharge location and the seep classification is summarized in Table 8.1-1. Less intensely altered seeps occur in rocks of the Hazelton group and chlorite-propylitic alterations, and intensely altered seeps occur in quartz-sericite-pyrite alterations and intermediate argillic alterations.

Table 8.1-1. Groundwater Seep Classification

Deposit	Seep	Alteration	Deposit	Seep	Characteristics
Kerr	K-1	-	Mitchell *(cont'd)*	MS-G	Intensely altered
	K-2	-		MS-C1	Intensely altered
	K-3	-		MS-C2	Intensely altered
	K-4	-		MS-C3	Intensely altered
	K-5	-		MS-C4	Intensely altered
Sulphurets	S-1	undetermined		MS-D	Intensely altered
Mitchell	MN-A	Less intensely altered		MS-H	Less intensely altered
	MN-B	Less intensely altered		MS-I	Less intensely altered
	MN-C	Less intensely altered		MS-J	Less intensely altered
	MN-D	Less intensely altered		MS-M	Less intensely altered
	MS-A	Intensely altered		MS-S	Less intensely altered
	MS-B	Intensely altered		MS-T	Less intensely altered
	MS-E	Intensely altered		MS-U	Intensely altered

8.1.1.1 pH, Sulphate, Acidity, and Alkalinity

The pH of all Kerr and Sulphurets Deposit seeps was acidic. The pH at the five Kerr Deposit seeps ranged from 1.25 at K-5 to 7.29 at K-3. The pH at K-4 became more acidic from June to August in 2010 and 2012

(from 3.2 to 2.4 and 3.7 to 2.8, respectively). The pH at the Sulphurets seep was 6.5. The pH at all Mitchell Deposit seeps was acidic. Less acidic pH values typically greater than 4 were observed in less intensely altered seeps. Seasonal trends were not observed for those seeps with multiple samples within one year (Figure 8.1-1). Ted Morris and McTagg seeps were near neutral from 2009 through 2012.

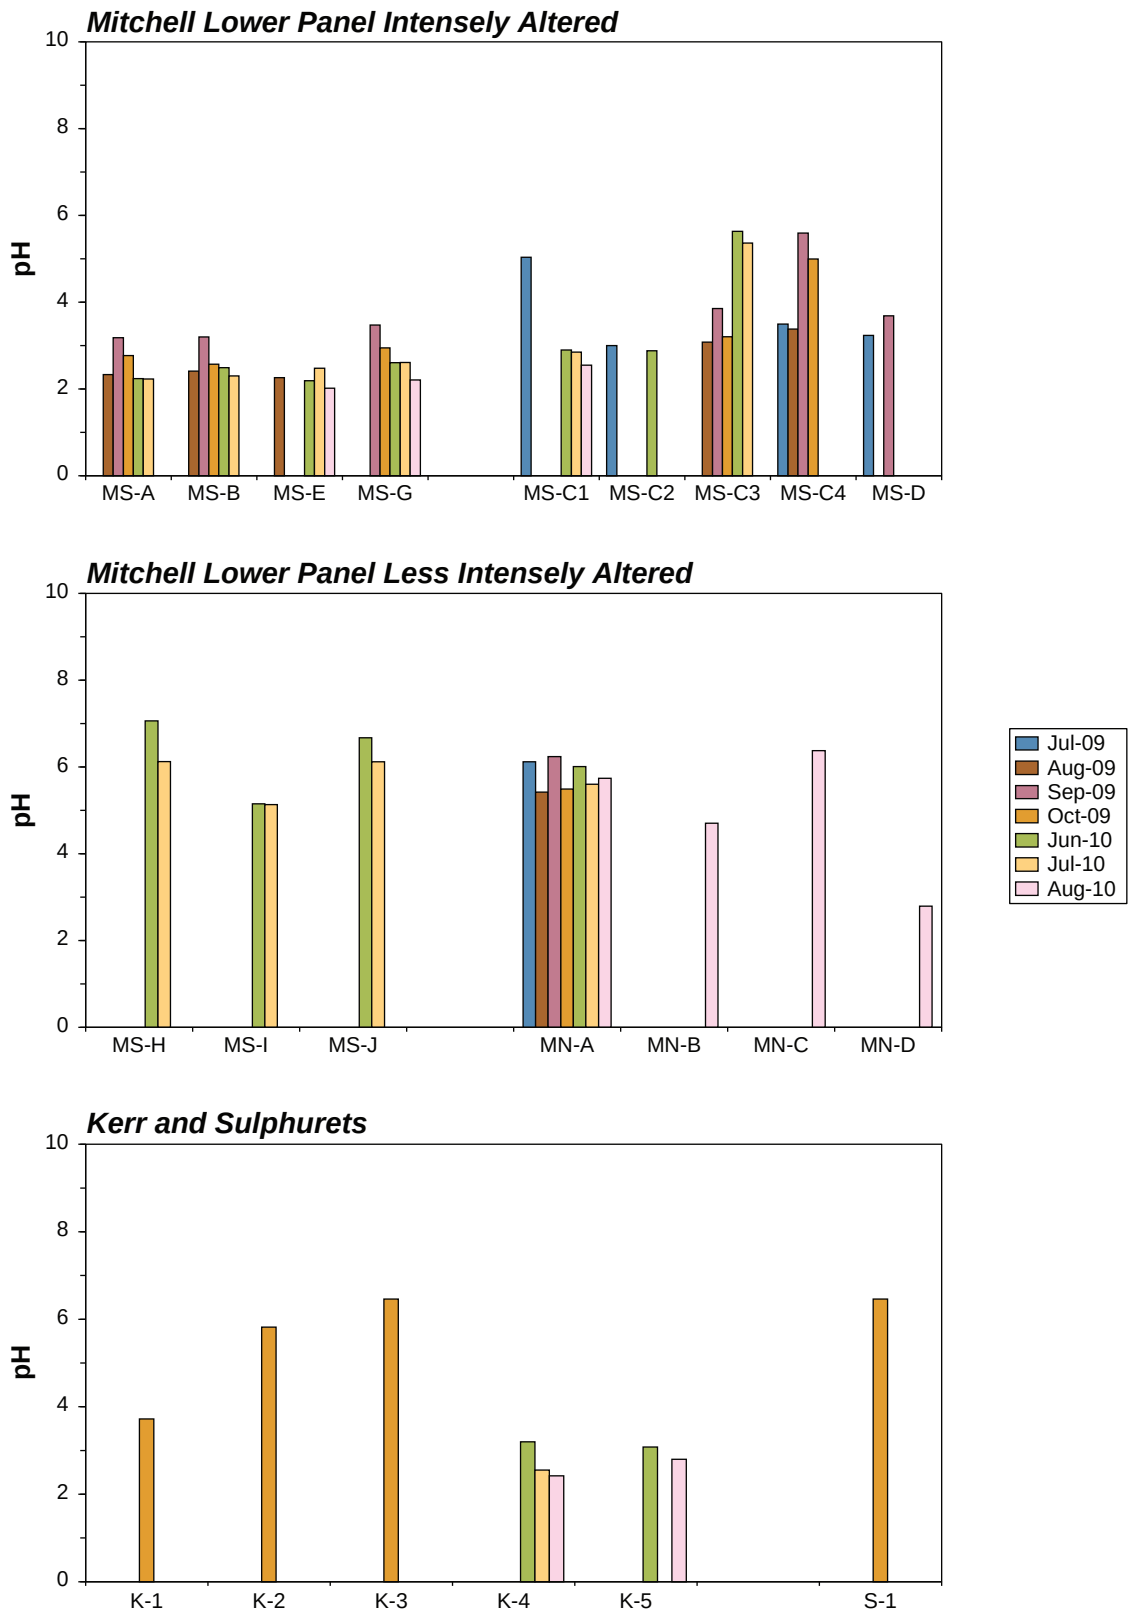
The sulphate concentrations were elevated at the Kerr seeps, ranging from 60 to 950 mg/L. Sulphate concentrations increased from June to August in 2010 and 2012 at K-4, coincident with decreases in pH. Sulphate concentrations ranged from 110 to 7400 mg/L in Mitchell South seeps. Sulphate concentrations were more moderate in Mitchell North seeps ranging and from 23 to 275 mg/L. Ted Morris and McTagg seeps had sulphate concentrations between 60 and 1500 mg/L (Figure 8.1-2).

Acidity and alkalinity at the Kerr seeps typically mirrored the pH with greater acidity and alkalinity below the detection limit measured at K-4 and K-5 with pH values less than 3. Acidity was greatest at intensely altered seeps reflecting low pH values, and lowest at less intensely altered seeps. Alkalinity was frequently below detection at intensely altered seeps, and ranged from below detection to 50 mg/L $CaCO_3$ at less intensely altered seeps (Figures 8.1-3, 8.1-4).

8.1.1.2 Elements that Contribute to Acidity

Total aluminum concentrations were elevated at all Kerr seeps except K-2, and ranged from 0.005 to 8.8 mg/L. Dissolved aluminum represented the majority of the aluminum in the seeps. Aluminum concentrations closely reflected the seep pH and greater concentrations were observed at lower pH values, especially below pH 4 (Figures 8.1-5, 8.1-6).

Total aluminum concentrations exceeded CCME water quality guidelines at all Mitchell Deposit seeps. Seasonal trends across seeps were not observed. The highest aluminum concentrations were observed at Mitchell South seeps, and concentrations were two to three orders of magnitude higher than at Mitchell North, Kerr and Sulphurets seeps. Dissolved aluminum represented the majority of the aluminum in the Mitchell seeps (Figures 8.1-5, 8.1-6).



Total iron concentrations were more comparable across the range of pH observed at the Kerr seeps, and ranged from 7 to 78 mg/L. Total and dissolved iron were below the detection limit at the Sulphurets seep (Figures 8.1-7, 8.1-8).

Total iron concentrations in the intensely altered seeps ranged from 5 to 2,400 mg/L, whereas total iron in the less intensely altered seeps ranged from below detection to 24 mg/L. Dissolved iron represented the majority of the iron in the Mitchell seeps (Figures 8.1-7, 8.1-8).

Total manganese concentrations at the Kerr seeps closely reflected the trend in iron concentrations, and ranged from 0.3 to 4 mg/L. Total manganese was below detection at the Sulphurets seep. The total manganese ranged from below detection to 11mg/L at Ted Morris and McTagg seeps. Total manganese concentrations were low in Mitchell North seeps, ranging from below detection to 0.89 mg/L. Manganese in Mitchell Southseeps ranged from 0.01 to 33 mg/L (Figure 8.1-9).

8.1.1.3 Barium

Barium concentrations were similar across Kerr and Sulphurets seeps, ranging from 0.005 to 0.04 mg/L. Barium concentrations were similar across all Mitchell seeps, ranging from 0.004 mg/L to 0.06 mg/L. The lowest barium concentrations were observed for Mitchell South seeps which had the lowest pH and highest sulphate concentrations (Figure 8.1-10).

8.1.1.4 Trace Elements

A statistical summary of the elements with elevated concentrations at the deposit seeps is presented in Table 8.1-2. The Sulphurets seep was not included as only one measurement was made. The concentrations of total trace elements are graphically presented in Figures 8.1-11 to 8.1-24.

In general, the trace element concentrations of the seeps are very high. These concentrations may represent site-specific equilibrium maximums. General seasonal trends were observed in the Kerr and Mitchell seeps. Concentrations increased throughout the summer of 2010 at the K-4 and K-5 seeps, reflecting decreases in pH. Concentrations typically decreased throughout the summer at the Mitchell seeps, which may reflect the flushing of oxidation products accumulated over the winter low flow period.

8.1.1.5 Elements Associated with the Neutralization Potential

Calcium and magnesium concentrations were similar across Kerr and Sulphurets seeps with concentrations that ranged from 36 to 340 mg/L, and 2 to 19 mg/L for calcium and magnesium respectively. Calcium and magnesium concentrations increased throughout the summer at the K-4 and K-5 seeps (Figures 8.1-23, 8.1-24).

Calcium concentrations were comparable across IARG and QSP seeps, ranging from 60 to 200 mg/L. Magnesium concentrations were more variable within each individual seep, and concentrations ranged from 4 to 80 mg/L. Calcium and magnesium concentrations were lower at the CL-PR and Hazelton Volcanics seeps. Calcium and magnesium concentrations tended to decrease throughout the summer at the Mitchell seeps (Figures 8.1-23, 8.1-24).

8.2 SEEP FLOW RATES

Seep flow measurements were conducted for selected seeps in September and October 2009 and for all seeps where geochemical samples were obtained in July 2010. The flow rates measured and calculated for seeps are presented in Table 8.2-1. A comparison of the flow rates for each of the seeps highlights the variability in the seep discharge that is a result of variable precipitation, infiltration rates, and flow paths. There is no clear relationship between the flow rates and temporal variability, as some seeps have higher flow rates in the fall while others have higher flow rates in the summer.

For Kerr Deposit seeps, the measured flow rates ranged from 0.03 L/s for seep K-3 to 6.4 L/s for seep K-1. Many of the higher elevation seeps in the Kerr Deposit are ephemeral.

For Mitchell Deposit seeps, the flow rates range from 0.01 L/s for seep MS-E in July 2010 to 127.20 for Seep MS-A in September 2009.

Seep flow rates in the Ted Morris Creek Valley were consistently lower in October 2009 than in July 2010. The flows in October 2009 ranged from 0.83 L/s (TM-E) to 7.34 L/s (TM-B) and in July 2010 ranged from 1.02 L/s (TM-E) to 8.13 L/s (TM-B).

9. Conclusions

The KSM Project has two geographically separated areas: (1) the Mine Site and (2) the Process Plant and TMF Area. These locations will be accessed by new access roads built from the Eskay Creek Mine Road and Highway 37. Samples of waste rock, tailing, non-deposit material, and groundwater seeps were collected for analysis between 2008 and 2012.

There were 2,030 samples of waste rock and potential pit wall material collected from diamond drill holes. These samples underwent static ABA, leachate, and kinetic tests. The ABA test results have been collected from all model codes used in the mine waste schedule. Adjusted SNPR values less than 2.0 were reported for 82% of Kerr samples, 43% of Sulphurets samples, 75% of Mitchell upper panel samples, 92% of Mitchell lower panel samples, and 92% of Iron Cap samples. The only model codes with median adjusted SNPR values greater than 2.0 were Sulphurets UP Hazelton, Sulphurets Monzonite, Sulphurets Undefined, and Mitchell Monzonite. The 40 humidity cell kinetic tests represent 99% of Kerr waste rock, 36% of Sulphurets waste rock, 94% of Mitchell waste rock, and 100% of Iron Cap waste rock. Aluminum, cadmium, copper, selenium, and zinc were the elements in kinetic test leachate that were most frequently elevated across various model codes and under both near-neutral and acidic pH drainage conditions. NAG leachate testing indicated that the sulphide minerals were the primary source of the cadmium and copper, but not the aluminum, selenium, or zinc.

Static ABA testing indicated that the Mitchell Sulphide and Rougher/Sulphide tailing are likely PAG due to the presence of sulphide minerals (pyrite) as these materials represent tailing that has not gone through the sulphide destruction circuit. Seventeen kinetic tests were initiated on tailing material. Leachate from the testing indicated that aluminum, arsenic, cadmium, copper, fluoride, selenium, sulphate, and zinc were elevated most frequently across various tailing types and under both near-neutral and acidic pH conditions.

Sixty-one overburden and 161 rock samples were collected from non-deposit Project regions. Overburden material located outside the proposed Mitchell Pit has a mean and median SNPR value greater than 4.0 and is classified as not-PAG. Based on adjusted SNPR values, only non-deposit rock material from TCAR, MTDT, and Sulphurets Laydown Area has a low potential for acid generation. SFE and MWMP leachate tests produced leachate with elevated concentrations of nitrite, sulphate, aluminum, arsenic, boron, cadmium, chromium, cobalt, copper, iron, lead, manganese, molybdenum, nickel, phosphorus, selenium, vanadium, and zinc.

Groundwater seeps from Kerr, Sulphurets and Mitchell Deposits, McTagg Creek Valley, and Ted Morris Creek Valley were sampled in 2009, 2010, and 2012. The seeps were acidic and had high metal concentrations representing site-specific maximums.

Note: values in blue are calculated

When reported as below DL half DL was used

highlighted cells are material analyzed in 2011 and might have had too much time to oxidize in storage

Note: values in blue are calculated

When reported as below DL half DL was used

highlighted cells are material analyzed in 2011 and might have had too much time to oxidize in storage

Appendix 5.1-1. Static Tests Results and Statistical Summary for the Kerr, Sulphurets, Mitchell and Iron Cap Deposits

Note: values in blue are calculated

When reported as below DL half DL was used

highlighted cells are material analyzed in 2011 and might have had too much time to oxidize in storage

Note: values in blue are calculated

When reported as below DL half DL was used

highlighted cells are material analyzed in 2011 and might have had too much time to oxidize in storage

Note: values in blue are calculated

When reported as below DL half DL was used

highlighted cells are material analyzed in 2011 and might have had too much time to oxidize in storage

Appendix 5.1-1. Static Tests Results and Statistical Summary for the Kerr, Sulphurets, Mitchell and Iron Cap Deposits

Note: values in blue are calculated

When reported as below DL half DL was used

highlighted cells are material analyzed in 2011 and might have had too much time to oxidize in storage

Note: values in blue are calculated

When reported as below DL half DL was used

highlighted cells are material analyzed in 2011 and might have had too much time to oxidize in storage

Note: values in blue are calculated

When reported as below DL half DL was used

highlighted cells are material analyzed in 2011 and might have had too much time to oxidize in storage

Appendix 5.1-1. Static Tests Results and Statistical Summary for the Kerr, Sulphurets, Mitchell and Iron Cap Deposits

Note: values in blue are calculated

When reported as below DL half DL was used

highlighted cells are material analyzed in 2011 and might have had too much time to oxidize in storage

Note: values in blue are calculated

When reported as below DL half DL was used

highlighted cells are material analyzed in 2011 and might have had too much time to oxidize in storage

Note: values in blue are calculated

When reported as below DL half DL was used

highlighted cells are material analyzed in 2011 and might have had too much time to oxidize in storage

Note: values in blue are calculated

When reported as below DL half DL was used

highlighted cells are material analyzed in 2011 and might have had too much time to oxidize in storage

Note: values in blue are calculated

When reported as below DL half DL was used

highlighted cells are material analyzed in 2011 and might have had too much time to oxidize in storage

Note: values in blue are calculated

When reported as below DL half DL was used

highlighted cells are material analyzed in 2011 and might have had too much time to oxidize in storage

Note: values in blue are calculated

When reported as below DL half DL was used

highlighted cells are material analyzed in 2011 and might have had too much time to oxidize in storage

Note: values in blue are calculated

When reported as below DL half DL was used

highlighted cells are material analyzed in 2011 and might have had too much time to oxidize in storage

Note: values in blue are calculated

When reported as below DL half DL was used

highlighted cells are material analyzed in 2011 and might have had too much time to oxidize in storage
